PRESIDENTIAL ADDRESS AT THE OPENING CEREMONY OF THE 39TH ANNUAL CONFERENCE OF THE HORTICULTURAL SOCIETY OF NIGERIA (HORTSON) HELD AT THE COCOA RESEARCH INSTITUTE OF NIGERIA, IBADAN, OYO STATE ON 14TH - 18TH NOVEMBER, 2021

Dr. Usman Ibrahim
President-in-Council, Horticultural Society of Nigeria

The President of the Federal Republic of Nigeria
The Honorable Minister of Agriculture
The Honorable Minister of Education
The Executive Governor of Oyo State, Engineer Abiodun Oluseyi Makinde
Members of Federal Parliament and Heads of Federal MDAs
Members of State Executive Councils, State Parliament, Heads of State MDAs
Royal Fathers
Executive Secretary, Agricultural Research Council of Nigeria, Prof. Sharubutu Garba Hamidu
Executive Director, Cocoa Research Institute of Nigeria, Dr. Patrick O. Adebola
Acting Executive Director of NIHORT, Dr. E. I. Nwanguma
Keynote Speaker, Professor Fatunbi A. Oluwole
Lead Paper Presenters: Professor Shehu Abdul Rahman (FHSN), Professor I.O.O. Aiyelaagbe (Past PIC and FHSN), Prof. Sharubutu Garba Hamidu, Engineer (Mrs.) Omolara Olorode and Dr. Casey Sclar Executive Director APGA
Distinguished Fellows of HORTSON
All Invited Guests
The Chairman and Members of Local Organizing Committee
Respected Members of HORTSON and Conference Participants
Members of the Press, Ladies and Gentlemen

It is a great pleasure, honor and privilege to deliver this address and welcome you to the 39th Annual Conference of HORTSON taking place at Cocoa Research Institute of Nigeria (CRIN) located in the ancient city of Ibadan, the political headquarters of Yoruba land. Ibadan is ranked among the most peaceful cities in Nigeria and highly accommodating to visitors. You are, therefore, highly welcome to the capital city of the pacesetter State and to CRIN.

I want to thank the Executive Director of CRIN, Dr. Patrick O. Adebola, for hosting this year's conference. I want to assure you that our Executive Director, who is also a member of this great society, has made full arrangements for us to have an enjoyable experience throughout our stay and also go home with Cocoa, Coffee, Cashew, Kola and Tea.

The theme of this year's conference is: "the role of horticulture in food security and sustainable health in era of climate change and Covid-19 pandemic". This theme is coined taking into consideration the increasing demand for horticultural crops and the pressing needs for prevention and treatment of communicable and non-communicable diseases. The Covid-19 pandemic is putting diets and food security in jeopardy around the world with markets, affordability, and access to healthy and nutritional food out of reach. Evidence shows that horticulture is a notable solution for improved food security. Foods such as fruits, vegetables and spices play key roles in the health and well-being of families and communities. Sustainable horticultural production aims to produce nutritious and healthy foods, while reducing negative environmental impacts, conserving natural resources, and enhancing healthy ecosystem services.

Climate change, environmental degradation and stagnating yields threaten crop production and world food security. It is now recognized that the enormous gain in agricultural production and productivity achieved through the green revolution were often accompanied by negative effects on agriculture's natural resource base. These negative effects are so serious that they jeopardize its productive potential in the future. It is also clear that the current food production and distribution systems are failing to feed the world. Given the current and the increasing future challenges to our horticultural crop supply and to the environment, sustainable horticultural production is emerging as major priority for policy makers and international development partners.

The population of hungry and malnourished people in the world stands at about 1 billion. There is a need for a major increase in food production to feed a population of 9 billion people by 2050. This can be achieved by doubling crop production in developing countries like Nigeria. However, there is decreasing availability and more competition for land and water, increasing urbanization and shift to peri-urban production, changing consumption patterns, and climate change. Increasing crop production is usually associated with increase in pesticides and fertilizer use, plus subsidiary elements such as the supply chain and transportation.

Currently, in order to increase production, many farmers in Nigeria use conventional chemical control methods and cultural methods to control plants infestation by pests. It has, however, been recorded that these methods are not an environmentally friendly option for pest management due to indiscriminate use and disposal of pesticides wastes which poses major threat to the environment. The indiscriminate use and disposal use of pesticides has resulted in its persistence in the environment, thereby affecting the ecosystems and non-targeted organisms including humans and animals. These pesticides are known to be major causes of cancers, cardiovascular diseases, dermatitis, birth defects, morbidity, impaired immune function, neuro behavioural disorder and allergy, which are public healthcare challenges in Nigeria. Whereas the key concern should be how to increase production sustainably, without causing damage to vital natural resources, or to the ecosystem in general. Thus, there is the need for production systems that will take into considerations health, environmental, institutional, and social principles.

It is our role, as horticulturists, to provide farmers with adaptable and relevant technologies, and ensure that governments provide them with enabling policies, infrastructural and institutional support. It has now become obvious to me, as a horticulturist, that we need to expand the scope of horticulture beyond the growing and eating of foods. We need to find a political voice, align closely with social movements and focus on developing grassroots and community based alternative horticultural production systems that are trans-disciplinary, participatory and action oriented to be most effective in bringing about changes that are urgently needed. We are the change makers who can make a difference.

In order for our society to champion the needed changes, we have developed a strategic plan for the society which will cover 2020-2027, when the society will be 50 years old (1977-2027). We have also developed a draft document for a proposed "Council for Regulation of Horticulture (CORHORT) in Nigeria". This document has been reviewed by various stakeholders. A copy of the draft document is being circulated for review, corrections, and observations. You can send all your observations to info@hortson.org.ng or to any Council member.

The society is proposing to organize a National Summit that will bring all horticulturists in Nigeria together to discuss the way forward and to form a national technical review and implementation committee for CORHORT. The date for the summit will be communicated. We have also developed partnerships with many key organizations that include the International Society for Horticultural Science, American Society for Horticultural Science, American Public Garden Association, Agriculture to nutrition Community of Practice, Agriculture Nutrition and Health Academy, Longwood Gardens, Federal and State Ministry of Agriculture and Private Agricultural Companies inorder to further enhance our ambition of horticultural and agricultural development in Nigeria.

Over the next three days, more than 250 researchers, policy and programming experts working in all areas of horticulture will gather to learn, share, and innovate. Over 280 scientific presentations would look at:

a) Public horticulture for sustainable environment, health, and economic development
b) Combating horticultural enemies for human sustainability.
c) Ensuring availability of horticultural produce through value addition and preservation.
d) Development of horticultural platforms for information dissemination and technology transfer.
e) Forest horticulture, medicinal and aromatic plants utilization.
f) Climate and crop modelling for the advancement of horticultural crop production.
g) Gender and social economic issues in horticulture.
h) Role of government in horticultural transformation in a developing economy.

I very much encourage you to make the most use of this opportunity to gain new knowledge and skills and foster new inter-disciplinary collaborations. I am proud to present to you a programme pack full of skill-enhancing presentations, inspiring keynote speeches, thought provoking panel discussions and innovative presentations from researchers all over the country. As change-makers, I challenge everyone here to put at least one thing they have learned into action from this conference. I call on all to support our mission to CORHORT and the government at all levels to support horticulture in all its ramifications for the betterment of the country.

Finally, we have also created spaces for less formal interactions and learning, including cocktail, and social events at the same time observing the Covid-19 guidelines for meetings and conferences as prescribed by the PTF protocol on Covid-19.

It is with great thanks to our combined efforts that we can meet here in CRIN and push our ambitious agenda forward. I am grateful to our Local Organizing Committee. Thank you all for joining us for this exciting HORTSON conference! Wishing us a fruitful deliberation and safe trip back to our respective destinations.

Long Live Horticultural Society of Nigeria!
Long Live Cocoa Research Institute of Nigeria!
Long Live Oyo State!
Long Live the Federal Republic of Nigeria!

KEYNOTE ADDRESS

THE ROLE OF HORTICULTURE IN FOOD SECURITY AND SUSTAINABLE HEALTH IN THE ERA OF CLIMATE CHANGE AND COVID-19 PANDEMIC

Prof. A. O. Fatunbi
Forum for Agricultural Research in Africa (FARA)

ABSTRACT
Food and nutritional insecurity is a major developmental issue in African countries; it spans from future generations' economics, health, intelligence, and cognitive potentials. The problems of climate change and the Covid-19 pandemic have exacerbated the pandemic's negative effect, triggering a threshold of the adverse impact that requires urgent intervention. This paper explains the cause of food and nutritional security In Nigeria using a mixed method comprising a systematic review of recent published articles and analysis of the available dataset. Food insecurity in Nigeria is associated with household poverty status and influenced by the national state of insecurity and displacement due to civil disturbance. Available data did not clearly show the influence of the covid-19 pandemic of food production and marketing in Nigeria; it rather affected trade and indirectly household income. However, the changes in weather variables occasioned by climate change reduce the production and distribution of horticultural commodities. The study confirms that a functional production system for horticultural commodities using the agricultural innovation systems approach could significantly enhance food and nutritional security in Nigeria. Policy action to trigger the desired change will include investment in research, advocacy, and awareness creation around the consumption of underutilized indigenous commodities.

INTRODUCTION
Food insecurity is a major global problem with multidimensional causes and effects. Global statistics on food insecurity indicated that about 690 million people at the global level do not have sufficient food, and about 95% of these individuals reside in the developing countries of the world, mainly in Africa and Asia (FAO, IFAD, UNICEF, WFP and WHO. 2020). The state of hunger in Africa is a precursor of many other health and social problems; civil disturbances, violent crime, dangerous migration, and other social vices, directly and indirectly, link hunger and food insecurity (Caughron, 2016). *Food security* is defined as a situation when all people, always, have physical, social, and economic access to sufficient, safe, and nutritious food that meets their dietary needs and food preferences for active and healthy life (FAO, 2002). This definition remains the most popular among intellectuals, having taken up the various dimension of the issues. Clay (2002) documented the evolution of the definition of food security; it explicated the policy, social, economic, and governance dimensions of the issues. The four interrelated elements in this definition include. Availability, access, utilization, and stability; each of the elements is a composite of issues. While availability refers to the physical presence of food for consumption, it encapsulates the issues of quantity, quality, diversity of food. It also covers the primary issues of maintaining a productive farming system and management of natural resources. Access refers to the ability of users to obtain food physically; it covers the issues of market access for producers and consumers, the cost of production, and retailers' price for food items; in other definitions, this is referred to as affordability. Utilization covers the issues of diversity and nutrient quality in the right proportion to meet the body's needs for a healthy life. Implicit in this is also the base issues of processing, packaging, and storage to retain quality. Stability covers the need always to have a regular supply of food, irrespective of the seasonal variation in production. The need to ensure constant supply to prevent the forces of demand and supply from shooting up the consumer's price. Issues of food price policies and provision of infrastructures for strategic food reserve to cater for emergencies such as drought, flood, and fire. The notion of nutritional security was added to food security issues,

ISSN: 2814-0508

nutritional security refers to access to food with adequate quantity and number of nutrient elements in a balanced form to meet the need of the body for a healthy life (Ingram, 2020). The world committee on food security thus gave a broader definition of food an nutritional security as a state "when all people, at all times, have physical, social and economic access to food which is safe and consumed in sufficient quantity and quality to meet their dietary needs and food preferences, and is supported by an environment of adequate sanitation, health services and care, allowing for a healthy and active life" (FAO, 2012). The crave for nutritional security came up following strong observation of stunting and wasting in children as well as the development of obesity and other diseases including Diabetes 2 in adults. This situation is not necessarily due to lack of food but imbalanced consumption of calorie dense food commodities at the expense of nutrient dense food. The consequences of poor nutrition on societal health, economy, cognition of the labor force and intelligence of the future generation is a cause for concern (Prado and Dewey, 2016).

According to World Bank data, Nigeria is rated as the most populous country in Africa, with 206.1 million, about 16.5% of Africa's total population. The diversity of culture and languages in Nigeria is the highest on the continent, providing economic and social stability opportunities. However, the food and nutritional security statistics are poor and do not reflect the enormous potentials of the most populous country in Africa. Available data indicated that about 14 million Nigerians are experiencing severe food insecurity (Owoo, 2021). This situation is mainly due to a more aggravated poor economic situation due to climate change, Covid-19 pandemic, and growing insecurity. These climatic and social disturbances prevented farming activities leading to a reduction in food production and a high increase in the price of food commodities.

In most food crises across the globe, the initial household response tends toward reducing the consumption of nutrient-dense food commodities. These commodities are traditionally high valued and costly; they are mostly the sources of protein and essential vitamins, viz., meat, fish and other seafood, fruits, vegetables, and legumes. The attention is shifted from having nutritious food to having food on the table to maintain life; essentially, the more affordable high calory food items predominate at this stage. This has its effects on the health and wellbeing of the society at large and the development of children and infants. The cause issues for the current surge in Nigeria's food and nutritional insecurity status requires more intellectual inputs in devising a sustainable solution.

Traditional problem-solving efforts revolve around tackling the cause issues viz., climate change, insecurity, covid-19 pandemic and the more endemic poor agricultural sector productivity, poor infrastructure, and rural poverty. These are ongoing, but such an approach is time-consuming and costly. A complimentary response mechanism could be strengthening the food system for the production and consumption of nutrient-dense food commodities. It essentially points at the horticultural sectors with over 300 indigenous nutrient-rich fruits and vegetables. The indigenous food commodities also need to be explored as sources of nutrient-rich diet to generate a resilient food system.

This paper discusses the various options to leverage the advantages of the horticultural crops as solutions to the food and nutritional security problems in Nigeria in the face of climate change, the covid-19 pandemic, and other emerging constraints. The paper use mixed methods comprising of extensive literature review, data sourcing from popular public data repository.

CAUSE AND CONSEQUENCE OF FOOD INSECURITY IN NIGERIA

Food insecurity is endemic to the rural settings in Nigeria, mainly due to several factors that limit sustainable agrarian livelihood, which is the primary means of living for rural settings. Nigerians living in the rural area is 99.1 million, about 48.04 % of the country's population in 2020. This figure has increased from 46.9 million in 1971 to 99 million in 2020, growing at an average annual rate of 1.54%. This is due to the expansion of the peri-urban area into the rural settings and the associated growth of the middle class. The middle class currently constitute 23% of the population, 92% of these individuals have post-secondary education, and their priority is to provide their wards with higher education. These individuals live in a decent apartment, and 18% plans to move to the owned apartment (Robertson et al., 2016). Available statistics indicated that the rural to urban migration has increased at 4.5% per annual mainly due to migration searching for higher income and quality of life (World Bank, 2016). The reason for this relocation is the protracted lack of infrastructures such as road networks, health facilities, education, employment opportunities, access to input and output market. All these factors make rural life unappealing and trigger the protracted shortage in farm labor with its attending social and economic effects. Smith et al. (2017) reported a significant association of food insecurity with low household income, poor social capital, low educational level, low household income, and the country's GDP.

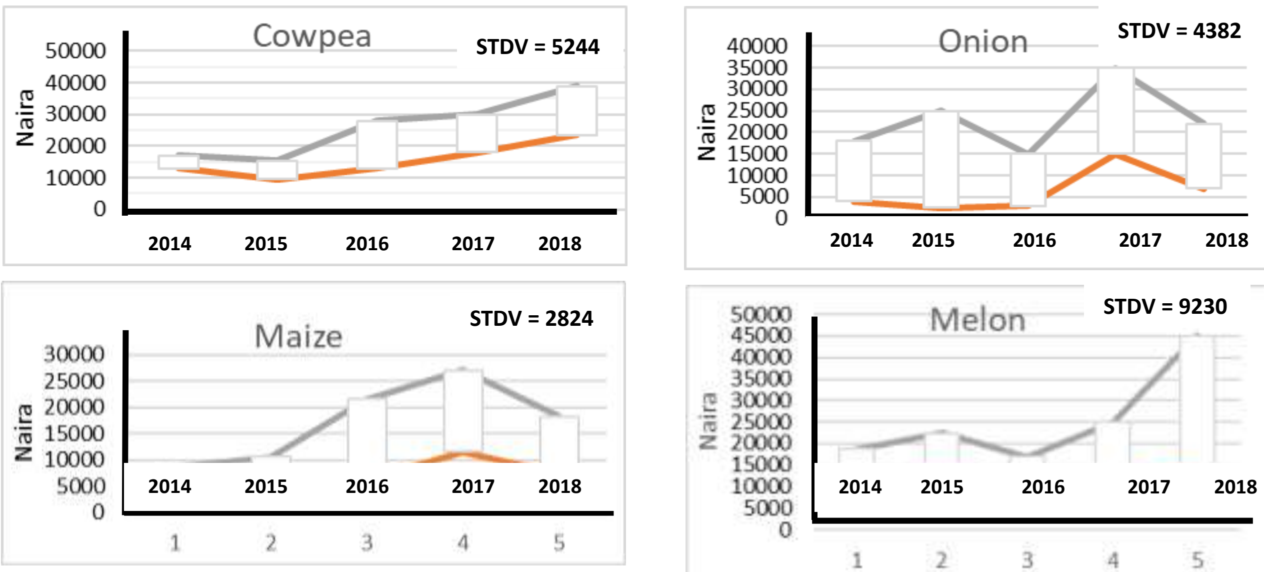

Figure 1. Fluctuations in market prices of food commodities in Nigeria

POVERTY LEVEL

Available data indicated that a strong relationship exists between food insecurity and poverty in Nigeria. Data from the Nigeria Bureau of Statistics indicated that 40% about 83 million Nigerians live below the poverty line of US $1.9 as of the year 2020 (Onyeiwu, 2021). This estimate uses the headcount poverty index; when multidimensional poverty measure was employed, about 98 million Nigerians, i.e., 47.3% Nigerians, live under poverty, and the more significant proportion is found in the northern part of the country. The food price inflation in Nigeria ranged between 30.52% - 17.64% (Figure 1), following the national price index report in 2021 (NBS, 2021). This contributed significantly to the total inflation in the country. It is noteworthy that the percentage of income spent on food in Nigeria ranked very high compared to other countries of equal standing. The world economic forum reported that an average family in Nigeria spends 56.4% of household income on food compared with America that spends 6.4%, Kenya 46.4, Cameroon 45.6%; and Algeria, 42.5% (Gray, 2016). A smart indicator of human development and wellbeing is the proportion of household income spent on food. The implication of this occurrence is the push of more families in Nigeria below the poverty line. Often, the pressure of insufficient household income affects the kind and quality of food consumed. In a study reported by Omotesho et al. (2008), accessibility to health facilities, household size, farm size, and household expenditure on food were critical determinants of a household's food and nutritional security status. These indicators are mainly pointing at the household capacity to produce and realize sufficient income to purchase food items over the lean period.

ISSN: 2814-0508

GROWTH OF THE MIDDLE CLASS

The growth in the middle-income class is a constant measure of development in a country. It is a pointer to some developmental factors that will emerge due to the demand of this class of individuals. The middle-income class is defined as individuals and households that fall between the higher and lower level of the socio-economic hierarchy (Hayes, 2020). They are mainly in the working class with the educational qualification that allows them to have a relatively good income, access to a comfortable house and vehicle. In Nigeria, the average middle-class income ranged between US$ 3 - $10 per day based on the World Economic Forum report of 2015; the lower percentile of $3 is consistent with the Africa Development Bank estimate that households that earn $4-$10 per day are in the lower middle class. Using the current exchange rate of $1 = N530, any household that earns up to N1,590per day could be regarded as fitting into the middle-class category. The 2015 estimate is outdated, and a new range is needed for Nigeria due to its recent financial downturn and fluctuation in the currency rate.

The bottom-line effect of the growth in the middle class is the change in food consumption patterns and the increase in demand for rich and more appetizing food commodities. The effect of this rise is always a sharp increase in price and unavailability of the commodities to meet the new demand. This will also have a multiplier effect on the industries and the national economy in the net importers of food like Nigeria. (Euromonitor, 2013)

INCOME LEVELS

The general income level is a significant contributor to food and nutritional security; it refers to the available purchasing power an individual or household could muster to acquire necessities such as food, clothing, housing, and health facilities. Income disparity is associated with food insecurity (FAO, 2019). Most countries with high-income disparity also have low per capita income and low purchasing capacity for food. Income disparity occurs when members of the working force do not get the same share of the economy's value. (Karmakar and Sarkar, 2013). When the disadvantaged population increases, the capacity to access nutritious food decreases, and insecurity increases within the system. The Gini coefficient in Nigeria is in the margin of 35.1; it is 31.9 in the urban area and 32.8 in the rural area (Figure 2). Income disparity in Nigeria is high; popular data suggests that more than 41% of the population is living below the poverty line.

Rural poverty is a cause for concern, significantly where the urban, rural migration is increasing. An earlier report indicated that the depth of rural poverty in Nigeria is 33% compared to urban poverty at 23% (Anyawu, 2006). The more significant proportion of the Nigerian labor force is in the agricultural sector, and they reside in the rural area; the poverty status of the rural household is indicative of the sector's performance. World Bank (2014) reported the likely effect of the increase in agricultural productivity on the poverty status of the farming household in Nigeria. A 10% increase in agricultural productivity will reduce the likelihood of being poor by 2.5% -3% in a typical Nigerian farming family.

EFFECTS OF CLIMATE CHANGE ON FOOD SECURITY IN NIGERIA

Climate change is a protracted global problem that is currently receiving broad-based attention; climate change is projected to affect the ailing agricultural sector in African countries. Nigeria is currently experiencing the debilitating effects of climate change on its agriculture; such effects will range from reduction in growing season due to fluctuation in the amount and distribution of rainfall, incidence of floods, dry spells, and progressive desertification. The surge in new pests and diseases with crops and livestock has been noticed in recent times. The button-line effect is reduced food production and the associated increase in food price (Ifeanacho, 2020).

The global effort at curtailing the effects of climate change in the agricultural sector is the development of the Climate Smart Agriculture (CSA) concept. The pillars of the CSA include mitigation, adaptation, and sustainable intensification. In the last decade, research actors, technocrats, and policymakers have taken up the CSA concepts and swung into actions to generate policies, systems, and technologies that are CSA compliant and respond to the need of the end-users.

RELATIVE EFFECT OF COVID-19 PANDEMIC ON FOOD AND NUTRITIONAL SECURITY IN NIGERIA

Covid pandemic had a harsh negative effect on the food and nutritional security in Nigeria. Due to the pandemic that affected food and fiber production processing and marketing, the already weak sector became weaker. The most vulnerable households were severely affected. Up to October 2021, the total reported infection in Nigeria was 207,618 and total death of 2,745, giving a recovery rate of 98.6%. Despite this impressive recovery rate, the national economy experienced a considerable downturn due to fiscal failures and breakdowns in arrangements and networks with partners from other countries. Poverty rates increased due to unemployment; many businesses and manufacturing companies also closed. The agricultural sector grew at 2.2% before the pandemic; this rate is far lower than the continental average of 3.4%. In 2020, the growth rate came down to 1.8%, leading to a shortage in supply and a hike in the food price.

The world Bank predicted that the Covid-19 pandemic would most likely push more than 5 million Nigerians below the poverty line due to its effects on the economy, in addition to the expected increase of 2 million due to population growth (Olurombi, 2020). The report specified that the Nigerian economy might shrink between 3.2% –

7.4% in 2021, while the poverty rate may increase from 40.1% in 2019 to 42.5% in 2020 (World Bank, 2020). The implications of covid-19 are traceable to the shortage in supply of imported commodities and disruption in the flow of export trade; resulting in high inflation with resultant effects on the prices of food commodities.

LEVERAGING THE BENEFITS OF HORTICULTURAL PRODUCTION SYSTEM FOR FOOD AND NUTRITIONAL SECURITY IN NIGERIA

The need to foster the availability, accessibility, and affordability of nutrient-dense food is vital to resolving Nigeria's food and nutritional security. The bulk of these food commodities falls under the horticultural crop category, and they are produced and marketed by smallholders in negligible quantity. Sixty-five percent of the cultivated land area in Nigeria is dedicated to the critical six energy commodities, viz., cassava, yam, maize, sorghum, rice, and millet. Cowpea and soybean, groundnut occupy a sizeable portion of the land, while a negligible portion is grown to horticultural crops (Bala, 2010).

The horticultural food commodities are fruits, vegetables, spices, and medicinal herbs. They are known to be rich in nutrients and are often depended upon as sources of essential vitamins and minerals rather than calories. Table 1 showed the nutrient content of selected horticultural crop commodities. It attempts to present two conventional commodities Maize and cowpea, just for comparison on nutrient composition.

Horticultural commodities are high valued crops for their nutrient content, and they are consumed as an accompaniment to main meals. They are a good income source for farmers and other marketers that engage in their value chain businesses.

The constraints to the production of horticultural crops are like those experienced by the other food crop commodity such as cereals, legumes, root and tubers, and tree crops. Ibeawuchi et al. (2015) reported the specific constraints confronting the development of horticultural commodities in Nigeria. The problems can be categorized into three broad groups, namely technological, institutional, and policy constraints. The three categories are not mutually exclusive as the component issues do have cross-cutting dimensions (Figure 3). Central to the development of the horticultural sector is the need to establish a functional research system to generate the required knowledge, technologies, and inventions. Horticultural research would respond in the affirmative to the low productivity of the different horticultural commodities and bridge the yield gap. The yield gaps are mainly due to the poor potential of the seeds, the production system, and the inefficient use of external inputs. Plaiser et al., (2019) reported that most vegetable producers in Nigeria recycle old seeds and use less fertilizer than the recommended rate. The best technologies for the smallholders' farmers should be packaged in the seeds by the researchers. Seeds should thrive under marginal nutrients, water, and flood; they should produce a good yield, have multiple resistance to pests and diseases, and possess desirable culinary properties. The breeders need to embrace the multistakeholder approach and run demand-driven breeding of improved varieties; this will facilitate meeting the needs of the technology end-users and adoption rate.

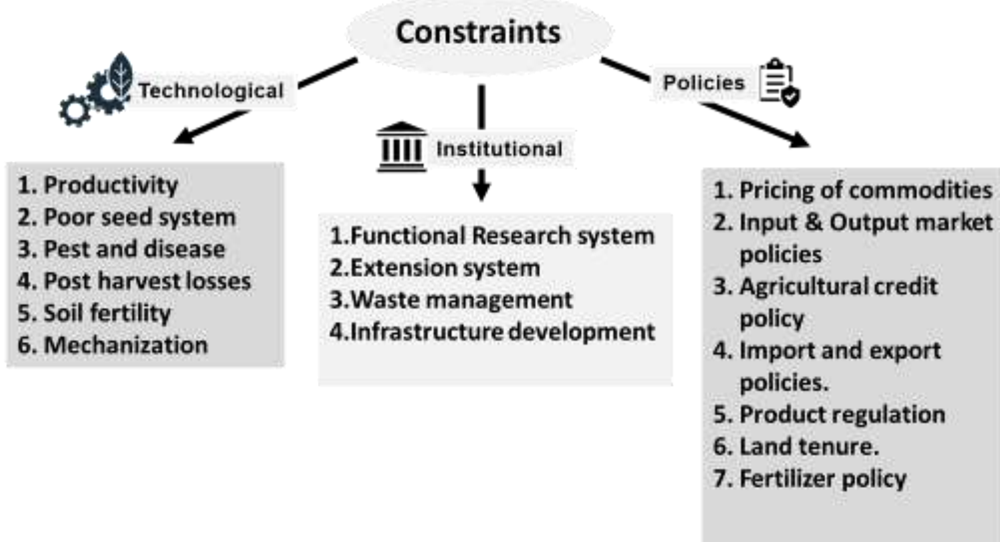

Figure 3. Category of constraint to the development of horticultural crops in Nigeria

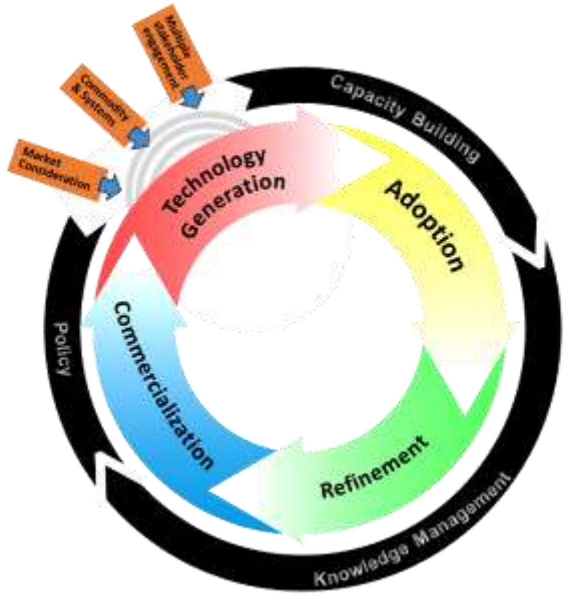
Horticultural crops are highly susceptible to insect pests and diseases; most often, agrochemicals are used to control the infestation and reduce yield loss. Research effort needs to give attention to pest-resistant breeding to develop varieties tolerant to diseases and resistant to pest attack. More than 20% -50% of horticultural crops produced in Nigeria are subjected to post-harvest losses (Muhammad et al., 2012). This leads to loss of income for farmers and traders; it is mainly due to a lack of processing facilities and preservation techniques. Leafy vegetables need to be consumed the same day they are harvested, while most fruits should be kept under certain conditions if they will still be suitable for consumption within two weeks of harvest. In a more advanced clime, cold storage facilities transport fruits and vegetables over a long distance to processing and storage facilities. Research efforts are further needed to develop a post-harvest handling method that could be used at the farmer's level to preserve horticultural commodities.

Efforts to enhance the contribution of horticultural crop commodities to food and nutritional security would require changes in institutional order. This could start from reorganizing the research and extension systems to be more functional in delivering knowledge and technologies to the end-users. In Nigeria, research funding is a significant constraint, the same as the fund for research equipment and other infrastructure. The researchers depend primarily on donor-funded projects designed in the direction of the interest of the development partners and, most time, not in the country's direction for sectoral growth. Bubu et al., (2017) recommended an intelligent funding strategy for agricultural research in Nigeria through the Agricultural Research Council of Nigeria (ARCN). One percent tax is requested from import duties on agricultural commodities to service research activities in its 17 research institutes. Innovative funding strategies like this are required to drive the horticultural research for delivery of outputs.

Furthermore, the research implementation method needs to be all-encompassing using the innovation systems approach. The multistakeholder approach needs to be institutionalized to ensure that research is demand-driven and the research output responds to the felt needs of the end-users. Other institutional changes will include revamping the agricultural extension systems and reintegrating them as part of the research organ in the country. This will remove the organizational gap and strengthen the communication between the researcher and the extension system for delivery. Within this form of institutional change, the mandate of the research organization will no longer be sole technology generation, but technology needs assessment, generation of solutions, dissemination, and facilitation of other enabling factors. With this model, the research organization's role will now be the holistic generation of innovation for impact.

The forum for Agricultural Research in Africa (FARA) worked with its stakeholders to develop the innovation to impact framework that could drive the restructuring of the research and extension system at the country level. Figure 4 depicts the core functions that should define a research system with an innovation outlook; it includes mobilizing the enabler factors, such as policy, capacity building, knowledge management, and private sector engagement as an intrinsic part of the organization's function. The central issues of technology generation, dissemination, adoption, lesson learning, technology refinement, and commercialization will now be an integrated whole.



.

Figure 4. Technology to Innovation Impact Pathway

The development of operational policies around the pricing of agricultural commodities is central to the sustainability of livelihood in the agricultural sector. Currently, the prices of agricultural commodities are subjected to the forces of demand and supply. This is counterproductive for producers of highly perishable horticultural commodities tied to the seasons of the year. Everyone moves to the market at the same time with their supplies, forcing down the price far below the cost of production. This is a major demotivating factor against the production of horticultural commodities in Nigeria. An informed policy is needed to ensure that the farmers can make a livelihood compliant margin from their endeavor. The use of the livelihood Compliant Pricing of Agricultural Commodities (LCPAC) could be a way to ensure sustainable livelihood from the agricultural endeavor. Other policy action will be on regulating input and output market to ensure fair pricing, regular supply, and eradication of the market lords and tyrants. There should be an effective agricultural credit policy that will ensure the availability of credit facilities at an interest rate suitable for the peculiarities of the agricultural sector. Import and export policies, regulation of product qualities, land tenure law, and fertilizer blending and marketing policies.

ROLE OF FORGOTTEN OR UNDERUTILIZED FOODS COMMODITIES IN ACHIEVING FOOD AND NUTRITIONAL SECURITY IN NIGERIA

Currently, about 7,000 plant species out of about 30,000 identified edible plant species had been used in the history of humanity to meet food needs (FAO 1998). Among these species, just 103 crops species provide 90% of the calories in the human diet, while only four of these (rice, wheat, maize, and potato) account for 60% of the human energy supply (Tontisirin and Bhattacharjee, 2010, Padulosi *et al.*, 2013). This suggests that many crop species are forgotten (i.e., underutilized, neglected, unimproved). They are underutilized in terms of consumption. They are neglected in terms of research, extension, commercialization, and conservation. The long-term neglect of these commodities has dramatically changed the national food system and led to a gradual decline in the consumption of the traditional food resources in many communities, as well as the conveyance of knowledge associated with the plants (Vorster *et al*., 2008; Bvenura and Afolayan, 2015). Based on this fact, there is a strong rationale for diversification of production and consumption in favor of the underutilized crop commodities as this would significantly contribute to improved nutrition and household food security (Jaenicke and Höschle-Zeledon, 2006).

The prevailing food and nutritional security situation in Nigeria is necessitating the need to think outside the box and explore options that are erstwhile ignored. Exploring and reintegrating forgotten or underutilized food commodities into the mainstream food system is a viable option. The term forgotten food refers to crop and livestock commodities that are erstwhile sources of food but have been neglected due to the advent of other food commodities. Forgotten foods are neglected and underutilized species, indigenous food commodities, orphan crops, etc. Padulosi *et al.* (2011, 2013) defined forgotten foods as crops that attract little attention or have been entirely ignored by agricultural researchers, plant breeders, and policymakers. Over millennia, the currently forgotten foods were the primary source of food (Demi, 2014). They are resilient and well adapted to the needs of farmers in agricultural environments. The adaptation of most forgotten foods to low-input agricultural systems and their nutritional composition has made them a reference point for having the potential to reduce food and nutrition insecurity, particularly for resource-poor households in Africa.

Furthermore, the adaptability of forgotten foods suggests that their cultivation is less damaging to the environment and addresses cultural needs. They also play an essential role in the cultural heritage of local communities (Mabhaudhi *et al*., 2016). Traditional foods are often a symbol of cultural heritage; they are part of the identities of diverse ethnic groups (Engler-Stringer, 2010; Sharif *et al*., 2016).

Agulana (2020) reviewed the importance of forgotten food to food and nutritional security in Nigeria; his work clearly showed that forgotten foods could have a much higher nutrient content than most nationally known species commonly produced and consumed. They stand out in commodity selection for nutrition-sensitive agriculture due to their great potential for improving nutrition and climate change resilience. The forgotten foods also play an important role in diversifying the food base to enhance food and nutrition security due to the varieties of nutrients the crop species can provide. Diversity of diets based on diverse crops delivers better nutrition and more significant health with additional benefits for human productivity and livelihoods. Also, because the crops serve as alternatives in crop failure, they readily fit into different cropping systems or schemes.

Despite the value that forgotten foods can contribute to Nigeria's food system, they have not attracted sufficient research and development attention. Therefore, collective actions are required to harness these potentials at the global, regional, and national levels. These actions involve creating awareness and communicating these foods' economic, nutritional, environmental, and cultural values to improve their consumption. They also provide the enabling environment for developing these foods through research, empowering farmers in production, and supporting the private sector in processing, value addition, and marketing.

CHARACTERIZATION OF FORGOTTEN FOODS IN NIGERIA

A prime crop commodity in a particular place could be termed as forgotten in another place due to the utilization status of the crop. Thus, the use of multiple factors to characterize forgotten food includes the prominence of the commodity in household food preference, the scale of production, market status, agronomy of the crop, nutritional quality, adaptation to agro-ecology, etc. Several authors have classified forgotten foods based on their understanding of the crop in their regions; Mabhaudhi *et al.* (2017) identified 13 priority forgotten foods in South Africa and categorized them into cereals, legumes, root and tuber crops, and leafy vegetables based on drought and heat stress tolerance and nutritional value. Dansi *et al.* (2012), in a survey conducted in 50 villages in the Republic of Benin, identified 41 neglected and underutilized species forgotten foods based on many factors, among which the extent and degree of consumption were paramount. In another study, Chivenge *et al.* (2015) identify and characterize forgotten foods in SSA with agronomic potential to those that can grow under water-scarce conditions, water requirements, and water productivity. The Africa Orphan Crop Consortium (AOCC) produced a compilation of different groupings and proposed that it will be most appropriate to characterize the forgotten food in Africa based on the following:

1. Period or life cycle: Annual, short-lived, and long-lived perennial
2. Consumable, edible parts or purpose of use:
    1. Fruit vegetable,
    2. Leafy vegetables
    3. Shrubs or small trees with edible fruits, nuts, and seeds
    4. Trees with industrial uses (Tianjin, dyestuff, etc.)
    5. Edible root and tubers
    6. Cereal grains
    7. Grain legumes
    8. Medicinal food crops
    9. Medicinal tree crops

A review of about 100 compiled forgotten foods found in Africa revealed that about 63% are horticultural crops; shrubs or small trees with edible fruits, nuts and seeds, fruit and leaves vegetables, while very few (about 1%) are in the category of annual industrial crops (Figure 5).

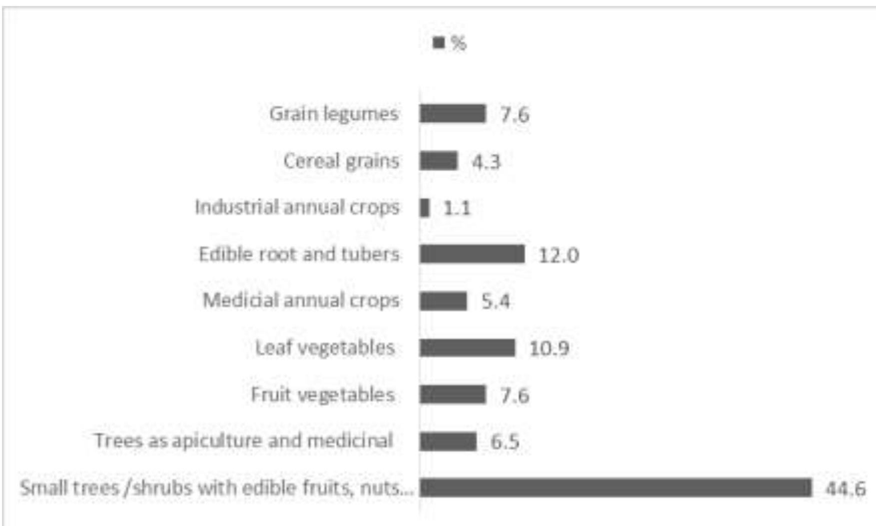


Figure 5. Characterization of 100 main Forgotten Foods

WAYS TO MAINSTREAM FORGOTTEN FOOD INTO NIGERIA FOOD SYSTEM

To mitigate the danger of food shortage and nutritional insecurity orchestrated by various constraints and lately aggravated by climate change, COVID-19, increased desertification, among others. There is the need to invest in life-saving crops that are resilient and well adapted to a broader range of environment and cropping systems. This will require a significant modification in the agricultural research and innovation approaches towards identified NUS in each region of Africa. As part of the global effort to reintegrate forgotten foods into the mainstream foods in Africa, FARA mobilized Africa stakeholders to develop the continental manifesto on forgotten and underutilized commodities; the following action plan is imperative for the reintegration of the commodities into the food system.

1. Awareness Raising for recognizing the values of forgotten foods by all in the society.
2. Creation of novel research development and networking

3. Promotion of concerted efforts in participatory plant breeding that will improve the adaptation of forgotten foods.
4. Development of sustainable seed systems that will enhance accessibility, availability, and affordability of high-quality seeds of forgotten foods.
5. Promote collection and conservation of genetic resources of forgotten foods for germplasm exchange.
6. Development of a specialized capacity instrument for NARES and relevant institutions towards the development of forgotten foods.
7. Facilitation of better access to markets, support to short supply chains, and alternative retail structures.
8. Encourage more advocacy and evidence-based policy change.
9. Introduction of knowledge on forgotten foods into teaching modules in educational programs.
10. Encouraging more advocacy and evidence-based policy change.
11. Adoption of new metrics and indicators to show the value of forgotten foods.
12. Fund and resources mobilization for investment on Forgotten Foods.

RECOMMENDATIONS AND CONCLUSION

Food and nutritional security are central developmental issue in the nation's life; it revolves around health, societal wellbeing, the integrity of the labor force, cognition potential of the posterity, and economic stability. Recent negative happenings in Nigeria's economic, social life, security status, political stability, and general societal wellbeing tend to put more pressure on the nation's food and nutritional security status. Available evidence suggests that climate change, the covid-19 pandemic, and national security are the primary factors aggravating the problems of food and nutritional insecurity in Nigeria.

The bottom line to food and nutritional security is the income level of the majority in Nigeria, vis-à-vis the price of nutritious food. Our review indicated that poverty is endemic in the rural area, and the urban to rural migration is on the increase in Nigeria due to the expansion of the urban in the peri-urban area and gradual reduction of the rural-urban land gap. The recommended effort to reduce poverty is to ensure the sustainability of the agrarian livelihood. We proposed the leveraging of appropriate measures to ensure the total factor productivity of our agriculture. We propose the adoption of Livelihood Compliant Agricultural Commodity Pricing to shield the price of agricultural commodities from the market forces of demand and supply. It will secure the livelihood of the smallholder farmers and secure the baseline income.

Efforts to eradicate the problem of food and nutritional insecurity in Nigeria will require a holistic approach. Such an approach will need to support the agricultural sector with interventions that will make it functional. The research systems may explore the innovation systems approach in its operations to ensure coherent generation of knowledge, technologies, and innovation. The role of the systems will not be limited to research only but also the identification of constraints, generation of solutions, dissemination, and lesson learning for societal improvement. It will also involve the mobilization of enabling factors.

Prime concentration on horticultural research and development is vital to ensure nutritional security. Our review indicated that 63% of the nutrient-dense food among Nigeria's forgotten or underutilized foods falls under the horticulture crop categories. It is essential to channel 63% of the research fund for food crops in this direction with demand for commensurate outcomes. We recommended that a specialized research program should be established for the reintegration of the forgotten food into the mainstream food systems in Nigeria with demand for intermediate development outcomes from the practitioners.

LEAD PAPER

ROLE OF RESEARCH AND DEVELOPMENT IN TRANSFORMING HORTICULTURE AND HORTICULTURAL INDUSTRY IN NIGERIA

Dr. Prof. Garba Hamidu Sharubutu
Executive Secretary ARCN

INTRODUCTION

Agriculture is the singular most important sector that can transform the economy of our great country to meet the growing demands for food, nutrition, industry and jobs. It forms the bedrocks for the diversification and economic recovery plan of the Federal Government and plays critical roles in the livelihoods of many individuals in Nigeria. The population of Nigeria presently stands at 200 million and it is one the fastest growing in the world. By 2050, these populations will double and Nigeria's population will be 450 million. This will bring in-balance between agricultural productivity and the population growth rates, which may exacerbate widespread food insecurity and poverty (Van der Waal 2020). Accordingly, increase in agricultural productivity is the key determinant to alleviate the foreseen circumstances and positively transform socio-economics and livelihood of Nigerians farmers.

CURRENT STATE OF NIGERIA'S AGRICULTURE

Crop production is the largest segment of Nigeria's agriculture, which accounts for about 87.6% of the sector's total output. This is followed by livestock, fishery and forestry at 8.1%, 3.2% and 1.1%, respectively. Agriculture remains one of the key sectors in Nigeria, contributing an average of 24% to the nation's GDP over the past seven years. In addition, the sector employs more than 60% of the country's labour force and more than 80% of Nigeria's farmers are smallholders, which accounts for 90% of Nigeria's agricultural produce (PwC Nigeria 2020).

Agriculture budget is only about 1.8% of the total national budget size, which significantly falls short of the 10% specified in the Maputo Declaration. Nigeria's agricultural trade deficit stood at N689.7 billion in 2019 compared to N549.3 billion in 2018, while Nigeria's cumulative agricultural imports stood at N3.35 trillion, four times higher than the agricultural export of N803 billion between 2016–2019 (PwC Nigeria 2020).

AGRICULTURAL RESEARCH SYSTEM IN NIGERIA

Agricultural Research Council of Nigeria (ARCN) was established in 2006 to coordinate and supervise agricultural research, training and extension in Nigeria. The mission of ARCN is to achieve significant improvements in agricultural productivity, marketing and competitiveness through generation of appropriate technologies, policy options and knowledge management of the agricultural research system. National Horticultural Research Institute, Ibadan, is one of the sixteen Agricultural Research Institutes under the purview of ARCN and has the national mandate for research in horticulture. The institute was established in 1975 and has two substations located in Mbato-Okigwe, Imo state and at Bagauda, Kano state.

GENERAL CONCEPT FOR RESEARCH AND DEVELOPMENT

Research and Development (R&D) involved generation of new knowledge that include activities undertaken to innovate and introduce new products, processes, services or improving existing ones. It is a systematic and creative work undertaken in order to increase the stock of knowledge, including knowledge of man, culture and society, and the use of this knowledge to devise new applications (Kadir *et al*., 2015). R&D activities include basic research, applied research and experimental development (Bronzini and Paolo, 2006) and it is the first stage of the product lifecycle during which a product team will conceptualize and assess the viability of a new product to decide whether it is worth taking or not. R&D is applied to every area of specialization and have different approaches but there are

ISSN: 2814-0508

some common factors, which include concept development, prototyping, IP management and technology licensing (Keith Fuglie *et al.,* 2015).

Research and Development represent a large and rapidly growing effort in both industrialized and semi-industrialized nations. The reason for increased emphasis on R&D is because it creates new or improved technology that in turn can be converted into a competitive advantage at the business, corporate, and social levels (Lawrence 2018). While the process of technological innovation is complex and risky, the reward can be high if the technology is safeguarded as proprietary and protected by patents, trade secrets, nondisclosure agreements, etc., in which case the technology becomes the exclusive property of the company or organization and the value is much higher (Sadraoui and Deguachi 2014). In agriculture, scientists actively seek to discover procedures that will increase livestock and crop yields, improve farmland productivity, reduce loss due to disease and insects, develop more efficient equipment, and increase overall food quality, among others.

AGRICULTURAL R&D KEY DRIVER FOR INCREASING PRODUCTIVITY

Research and Development in agriculture is designed to optimize total farm inputs to achieve maximum output both in terms of quantity and value. It leads to increased knowledge about high yielding crops; invention of drought resistant crops, which help in preventing crop failures in the event of drought; better ways of improving soil fertility, which leads to increased yield; introduction of advanced machines in production, which made the production process to go faster, and leading high quality and quantity of products within a short period of time. The advanced machines may include machines for tilling land like tractors, planting and harvesting machines. Agricultural R&D could also lead to the discovery of crop and livestock diseases, their causes, preventive and curative measures. It also leads to development of better preservation and storage methods and facilities that could help reduce post-harvest losses by the farmers. It also leads to development of better planting and farming methods and improved marketing services, which further leads to improved agricultural productivity.

OVERVIEW OF HORTICULTURAL INDUSTRY IN NIGERIA

Horticulture is the practice or science of growing fruits, vegetables, flowers and landscaping. Most fruits and vegetables are used as food while some are for seasoning of foods such as garlic, ginger, onion, amongst others. Nigeria as a country is unable to meet its domestic requirements for vegetables, fruits, floriculture, herbs and spices, dried nuts and pulses. Nigeria is a net importer of horticultural crops. In 2019, Nigeria imported a total of 80,227 metric tonnes of tomato paste valued at over 25 billion naira to bridge the deficit gap between supply and demand in the country (FAOSTAT 2021, Table 1).

Nigeria horticultural crops production has been increasing over the years. FAO data for ten of the most widely cultivated horticultural crops in Nigeria revealed increased production for most crops between 2009 – 2019 (Table 2). Tomato production rose from 1.75 million tonnes to 3.81 million tonnes representing 118% increase, while ginger production rose from 168,800 tonnes to 691.239 tonnes representing 309% increase during the same period (FAO 2021). This increase is largely due to increase in land areas for cultivation of these crops. Onion, peppers, citrus and mangoes have a marginal increase of 2.2 – 13.4% over the same period (Table 2).

A comparative study for yield of tomato in five African countries namely, Egypt, Kenya, South Africa, Senegal and Nigeria showed that all the countries have a declined yield over period 2009 – 2019 with South Africa and Egypt having the lowest decline (-3.1 and 4.4%, respectively), while, Kenya and Senegal had yield decline of 33.3 and 23.1%. respectively (Table 3). Nigeria produced the lowest yields for both 2009 and 2019 and showed a declined yield of 29% between 2009 and 2019 (Table2).

Table 1. Value of Nigeria's imports and exports of some selected fruits and vegetable in 2019

Commodity	Import value ($)	Export value ($)	Net import value ($)
Almonds shelled	779,000	1,000	778,000
Almonds, with shell	10,000	0	10,000
Apples	38,510,000	1,000	38,509,000
Fruit, cooked, homogenized preparations	481,000	0	481,000
Fruit, dried nes	86,000	45,000	41,000
Fruit, fresh nes	254,000	16,000	238,000
Fruit, prepared nes	1,629,000	358,000	1,271,000
Fruit, tropical fresh nes	6,000	0	6,000
Grapes	8,945,000	0	8,945,000
Juice, apple, concentrated	2,406,000	14,000	2,392,000
Juice, apple, single strength	1,217,000	288,000	929,000

Table 3. Comparative Yield of tomatoes in 5 African countries 2009 and 2019

Country	Crops	Yield t/ha		% Growth
		2009	2019	
Egypt	Tomato	40.8	39	-4.4
Kenya	Tomato	30.6	20.4	-33.3
South Africa	Tomato	69.2	67.1	-3.1
Senegal	Tomato	27.3	20.7	-24.1
Nigeria	Tomato	6.5	4.6	-29.0

Source: Based on FAOSTAT (2021)

A similar study for yields of citrus in five African countries namely, Egypt, Kenya, South Africa, Ethiopia and Nigeria (Table 3) showed a declined yield for Egypt and Kenya (-16.1 and -7.6%) respectively over a period 2009 – 2019. Ethiopia and South Africa have a modest yield increase of (18 and 20.7%) respectively, while Nigeria produced the lowest yields in both periods and had a marginal increase in yield (2.6%) between 2009 and 2019 (Table 4).

Table 4. Comparative Yield of fruit citrus in 5 African countries 2009 and 2019

Country	Yield t/ha		% Increase
	2009	2019	
Egypt	16.6	13.9	-16.1
Kenya	7.4	6.8	-7.6
South Africa	35.3	42.6	20.7
Ethiopia	6.4	7.6	18.0
Nigeria	4.9	5	2.6

Source: Based on FAOSTAT (2021)

Nigeria is importing large quantities of horticultural produce, among which tomato paste, apple and spices account for the large chunk of the import. More than 90,000 thousand tonnes of tomato paste was imported by Nigeria in 2009 but the figure dropped to about 80,000 tonnes in 2019 representing 11% decline during the ten-year period. Vegetables and spices import rose 120.6 and 62.4% respectively between 2009 and 2019, while apple import rose from a mere 52 tonnes in 2009 to 44,013 tonnes during the study period (Table 5)

ROLE OF R&D IN TRANSFORMATION OF HORTICULTURAL INDUSTRY

Transforming Horticulture and Horticultural Industry in Nigeria from the point of view of R&D advocates increased availability of generated improved technologies as well as accessibility and utilization of those technologies by farmers for increased food production, reduction of poverty, supply of raw materials to industries and improved livelihood of the farmers. Gaps in production of horticultural crops, including that between potential and actual yields obtained by farmers warranted continuous research for improved varieties, production and post-harvest technologies for increased productivity and farmers' income.

There is also the need for capacity building of farmers to understand how to face the challenges of social and economic barriers, regulations, access to finance and information, competition, their managerial capacities, market related risks, low bargaining power, vulnerability to economic shocks and business dynamics to be able to seize opportunities. Consequently, having in place entrepreneurial centres to cater for the practical needs of farmers/students will make them better equipped for a successful career in agribusiness.

Table 5. Import of major horticultural crops in Nigeria 2009 and 2019

Crop	Import (MT)		% Increase
	2009	2019	
Tomato paste	90,221	80,297	-11.0
Peppers dry	58	1,168	1913.8
Juice Orange	27	692	2463.0
Apples	52	44,013	84540.4
Spices	3,228	5,241	62.4
Vegetables	165	364	120.6

Source: Based on FAOSTAT (2021)

Therefore, to fast track the process of increased production and marketing of horticultural produce for economic exploitation, awareness of the economic, medicinal and nutritional values of these spices should be emphasized. Also, success in commercializing horticulture depends on the orientation of production to meet market demand and on the removal or reduction of a broad range of marketing constraints.

WAY FORWARD TO SUSTAIN R&D FOR TRANSFORMATION OF HORTICULTURE

The following should be done to maintain the positive and significant effect of agricultural R&D expenditure and R&D in other sectors.

1. Alignment of research in horticulture to government policies and priorities as was the case for import substitution enshrined in agricultural promotion policy should be encouraged and holistically implemented.
2. Increase the budgetary allocations to agricultural R&D so that more serious and high value agricultural research can be undertaken. Inekwe (2014) found that research and development expenditure had a positive significant effect on economic growth in countries.
3. Establish concrete collaborations between scientists and research institutions worldwide to encourage knowledge sharing and communication.
4. Employ and build capacities of agricultural research scientists, trained to facilitate serious agricultural research that can lead to more discoveries.
5. Provide terms and conditions that are favourable to agricultural research scientists in terms of remunerations and job security so as to motivate them to put more effort in their work.
6. Ensure that the knowledge generated through agricultural research is disseminated to the public by employing more agricultural extension officers. It has been established that improved varieties had a major positive impact on productivity growth (Fuglie and Maeder, 2015).
7. Intellectual property rights need to be enhanced through patents, copyrights and trademarks so as to encourage firms producing agricultural products and inputs to carry out agricultural research and spend more on agricultural research.
8. Ensure that more agricultural research institutions including private ones are established to increase the intensity of agricultural R&D.
9. Development of input and output markets structures and incentives that allow the full realization of the value of increased production.
10. Well-functioning and vibrant private sector that can manage, and allocate skill and capital to scale emergent success and drive long-term sustainable agribusiness growth.

CONCLUSION

Alignment of R&D in horticulture to government policies and priorities, effective utilization and proper targeting of available funds, establishment of private research outfits, establishment of intellectual property right and effective utilization of improved technologies will go a long way to transform the horticultural industry in Nigeria.

ABSTRACT

For millions of years, human survival and evolution depended on our ability to cope with the natural world; learning what was safe and dangers involve in negative emotional reactions to various natural stimuli. The complex symbolic and emotional ties that humans have with trees have important implications for the importance of sound urban forest management practices that impact not only quality of life on an ecological level, but on the human and cultural level. Urban forestry is the care and management of urban forests, i.e., tree populations in urban settings for the purpose of improving the urban environment. Recently, Global warming has become the major topic of discussion around the world, conserving the forest and wildlife in a sustainable manner is key to reducing the emissions of Green House Gas (GHG) and wildlife conservation from extinction. This review paper critically highlights the role of urban forestry in wildlife conservation and Green House Gas reduction.

Key words: Urban Forestry, Green House Gas, Wildlife, Conservation, Energy

INTRODUCTION

Urban forestry is the careful care and management of urban forests, i.e., tree populations in urban settings for the purpose of improving the urban environment. Urban forestry advocates the role of trees as a critical part of the urban infrastructure (Caves, 2004). Urban foresters plant, prune, maintain trees, support appropriate tree and forest preservation, conduct research and promote many benefits trees provide. Urban forestry is practiced by government and commercial arborists, environmental policymakers, city planners, consultants, educators, researchers and community activists (Campanella, 2003). Trees are usually selected, planted, trimmed, and nurtured by people, often with specific intentions, as when a tree is planted in a front yard to shade the driveway and frame the residence. The functional benefits provided by this tree depend on structural attributes, such as species and location, as well as management activities that influence its growth, crown dimensions, and health (Campanella, 2003).

The complex symbolic and emotional ties that humans have with trees have important implications for the importance of sound urban forest management practices that impact not only quality of life on an ecological level, but on the human and cultural level. People develop emotional attachments to trees that give them special status and value. For many, feelings of attachment to trees in cities influence feelings for preservation of trees in forests (Coder, 1996).

The social and even medical benefits of nature are also dramatic. Urban poverty is common to areas lacking green spaces. Visiting green areas in cities can counteract the stress of city life, renew vital energy and restore attention, and improve medical outcomes. Simply being able to see a natural view out of the window improves one's admiration of nature. Having regular access to woodland is desirable for schools, and indeed Forest kindergartens take children to visit substantial forests every day, whatever the weather. When such children go to primary school, teachers observe a significant improvement in reading, writing, mathematics, social skills and many other areas. Various methods are available to capture the value of urban trees, each designed to analyze a specific type of green space (individual trees, parks, trees on golf courses etc.) (Kaplan and Kaplan 1989; Kaplan 1992).

Environmental values of trees in urban areas: watershed, energy and air quality benefits

In the past, trees were often included in local plans primarily as beautification elements. Today many planners have realized that trees play a much greater role. They are a critical factor in human health and well-being, affecting the overall quality of life in communities. Over the past twenty years, urban tree researchers have learned that trees in urban areas improve air quality, conserve energy, reduce storm water runoff, increase property values, attract businesses, reduce stress, increase healing, and decrease crime. More recently, researchers at the Centre for Urban Forest Research have been able to place a dollar value on some of these benefits, such as storm water runoff, air quality, and energy conservation.

The Clean Water Act regulations require municipalities to obtain a permit for managing their storm water discharges into water bodies. Each community's program must identify which best management practices (BMPs) will be implemented to reduce pollutant discharge. Healthy trees with large leaves and rough surfaces can reduce the amount of runoff and pollutant loading in receiving waters. Trees control runoff at the source by intercepting and storing rainfall, reducing runoff volumes and erosion of watercourses, as well as delaying the onset of peak flows. Rainfall that is stored temporarily on leaf and bark surfaces is called interception. Intercepted water evaporates, drips from leaf surfaces, and flows down stem surfaces to the ground. Saturation generally occurs after 1 to 2 inches of rain have fallen (Xiao et al., 2000). Rainfall interception by large trees is a relatively inexpensive first line of defense in the battle to control nonpoint-source pollution when compared with more expensive solutions like retention basins.

Energy enhances economic growth and is an essential ingredient for quality of life. Greening cities with trees can help conserve this energy, and this technique is often a cost-effective solution. For example, the Centre for Urban Forest Research found that strategically planting 50 million more shade trees in California cities on the east and west sides of buildings will provide savings equivalent to seven 100-megawatt power plants (McPherson and Simpson, 2003). The cost of peak load reduction is $63/kW, considerably less than the $150/kW benchmark for cost effectiveness.

The amount of gaseous pollutants and particulates removed by trees depends on tree size and architecture, and local meteorology and pollutant concentrations. Uptake rates are high when pollutant concentrations and leaf surface areas are high. For example, in Western Washington, where air pollutant concentrations are low, annual O3 uptake rates for a 20-year old red oak and purple-leaf plum were 0.35 pounds and 0.13 pounds, respectively. In Los Angeles, where concentrations are higher, uptake rates for the Shamel ash and crape myrtle were 1.26 pounds and 0.19 pounds, respectively (McPherson et al., 2001). In the Chicago region, 51 million trees remove about 250 tons of PM10, 200 tons of O3, 100 tons of SO2, and 20 tons of carbon monoxide annually. This environmental service is estimated to have an annual value of nearly $10 million (Nowak, 1994).

Urban forestry, wildlife conservation and greenhouse gas reduction: the interrelationship

Human activities, primarily fossil-fuel consumption, are adding greenhouse gases to the 'atmosphere, resulting in gradual temperature increases. This warming is expected to have a number of adverse effects. With 50 to 70 percent of the world's population living in coastal areas, a predicted sea level rise of 6 to 37 inches could be disastrous. Trees have been recognized as important storage sites for carbon dioxide (CO2), the primary greenhouse gas (Nowak and Crane, 2002). At the same time, private markets dedicated to economically reducing CO2 emissions are emerging. Carbon credits are trading for$0.11 to $20 per metric tonne, while the cost for a tree planting project in Arizona was $19/metric tonne (McPherson and Simpson, 1999). As carbon reductions become accredited and prices rise, carbon credit markets could become monetary resources for community tree programs.

The concept of accommodating both humans and wildlife in the same area is nothing new. Humans have always lived with other animals.

However, over geologic time, human populations have increased and drastically extended their dominance on the landscape. Many plant and animal species that were once wild are now domestic. Ecosystems that evolved through millennia of natural processes and stochastic events have been severely humanized within decades. Many benefits can result from efforts to enrich and manage wildlife in urban forests. Native animals attracted to properly managed sites can provide recreational and educational opportunities for local residents. People involved in planning, installing and using areas managed for wildlife realize how decisions can directly influence environmental quality and are likely to develop a better land ethic. These areas also include the use of native plants that require less water and nutrients than exotic grasses and ornamental plants.

Living and non-living ecosystem components installed in urban areas help to restore the natural value of sites making them better places for native wildlife to live. In other words, management practices that would include adding native components would improve the habitats for much native wildlife. These components provide some of the essential requirements for animals: food, cover, water, and space (Herwitz, 2001).

CONCLUSION

Urban forestry provides sustainable forest practice that ensures that trees are managed and care for. This process ensures that there are enough trees in the urban environment to sink carbon dioxide which is a major GHG that is responsible for global warming, by promoting urban forestry water quality will be improved as well as clean energy and air quality. Furthermore, urban forestry ensures that the natural habitat of wildlife is intact to prevent extinction of endangered species.

ABSTRACT

Watermelon (Citrullus lanatus) belongs to the family Cucurbitaceae (Schippers, 2000), a vine-like (scrambler and trailer) flowering plant in West Africa. It is cultivated for its fruit. Its centre of origin has been traced to both the Kalahari and Sahara deserts in Africa (Jarret et al., 1996). In some African cuisines, however, watermelons are served as a cooked vegetable. Watermelon seeds are ground into flour and baked as bread in some parts of India. In addition, watermelon is also used as feed for livestock. The seeds and flesh are used in cooking; it has been taken to prevent and treat a wide range of ailments and diseases. Watermelon is effective in prevention of heart disease, high blood pressure, cancer, diabetes, as well as curing effect on coronary, liver and kidney disorders. It is good source of minerals, and vitamin C; half kg of fruit can satisfy our daily need in vitamin C. Other than 85% water content it contains 7-15% of sugar, also minerals, vitamins and little bit of proteins as well. Vitamins present are carotenes, vitamin B complex and traces of C vitamin required to boost our immune system. Mineral content present are potassium, magnesium, phosphorus, calcium, zinc, iron, and cuprum. It is a good source of carotenes and lycopens as well. This article reviews the importance of Watermelon (Citrullus lanatus) as potential natural sources for the development of novel drugs.

Key words: Watermelon, health benefit, vitamin C and vegetable

INTRODUCTION

The rapid increase in the risk of chronic illnesses such as renal failure and cardiovascular diseases has motivated experts, researchers, and health-conscious individuals to explore ways of using dietary interventions with potential health benefits that go beyond the provision of essential nutrients. Existing literature shows that watermelon is considered to be an important fruit with vital components with anticancer, antioxidant, and anti-inflammatory properties (Ijah et al., 2015; Choudhary et al., 2015).

Watermelon (*Citrullus lanatus*) is a scrambling and trailing vine belonging to the family Cucurbitaceae (Edwards *et al*., 2003). That is among the highest of plant families for number and percentage of species used as human food. The common name of watermelon is Tarbooz (Hindi and Urdu), Indrak (Gujarati) Kankana (Hausa). Watermelon is originated from Kalahari Desert of Africa but nowadays cultivated abundantly in tropical regions of the world. It has great economic importance with 29.6 million tonnes estimated production worldwide (Reetu and Tomar, 2017). Watermelon is an important fruit crop that is currently gaining recognition as cash crop good in the generation of income and provision of nutritional value. Watermelon flesh contains high quantity of vitamins, minerals and other antioxidant compounds which play important role in human metabolism and preventing human disease by acting as oxygen radical scavenger. Watermelon rind and seed also have many health benefits due to the presence of important amino acids citrulline, fibres, minerals and phenolic compounds.

Furthermore, watermelon is one of the commonly consumed fruits in many countries. It contains more than 91% water and up to 7% of carbohydrates. Watermelon is a rich source of lycopene and citrulline. It is highly nutritious rich in vitamins C and A in the form of disease-fighting beta-carotene. Watermelon is also rich in carotenoids such as lycopene, phytofluene, phytoene, beta-carotene, lutein and neurosporene. Additionally, watermelon has a number of essential micronutrients such as potassium. Its seeds are excellent sources of protein (both essential and non-essential amino acids) and oil (Adekunle et al., 2003). In Nigeria, though there are no official figures recorded for its production, the crop has a wide distribution as a garden crop, while as a commercial vegetable production; its cultivation is confined to the drier savanna regions of Nigeria (Anon, 2006).

Lycopene is a vibrant tetrapenic carotenoid with molecular formula of $C_{40}H_{56}$and contains 11 conjugated and 2 unconjugated double bonds (Fish et al., 2002) It is an acyclic isomer and open-chain analogue of β-carotene that undergoes *cis-trans* isomerization when interact with light, temperature and chemicals (Ollanketo et al., 2001). A great majority of studies have demonstrated that human blood serum contains both *cis*- and *trans*- isomeric forms of lycopene whereas the plants have only transconfiguration except watermelon (Klipstein-Grobusch et al., 2000; Tadmor et al., 2005). Lycopene has potential to prevent various chronic ailments like dyslipidemia, diabetes, oncogenesis, neurodegenerative diseases, osteoporosis etc. The protective aspects are ascribed to the singlet oxygen scavenging ability. Numerous metabolic syndromes arise due to high free radical's formation reacting with macromolecules thus oxidizing proteins, lipids and DNA. Lycopene protects humans from various pathogenic attacks responsible for an array of diseases (Ilic and Misso, 2012; Sesso et al., 2005). Several authors have reported that lycopene holds nutraceutical potential and being antioxidant provides protection against free radicals and oxidative damage (Krinsky, 1998; Rao and Agarwal, 1999; Choksi and Joshi, 2007). Free radicals are produced in the body during oxidation reduction reaction however, excessive production deteriorates body defense mechanism, cell membrane and organelles. These degenerative processes resulted in life threatening ailments (Humberto, 2000; Heber and Lu, 2002; PerkinsVeazie and Collins, 2006). The presence of large number of double bonds is responsible for its fairly high free radical scavenging or singlet oxygen quenching ability even better than α- and β-carotene, lutein and α-tocopherol (Rivero et al., 2001; Perkins-Veazie and Collins, 2004). Lycopene provides protection against degenerative disorders via mechanisms like gap-junction communication, gene function regulation, phase II drugmetabolizing pathways and carcinogenic metabolism (Arab and Steck, 2000; Collins et al., 2004). It has been established through epidemiological studies that lycopene plays a_role in maintaining normal cellular differentiation and division (Giovannucci et al., 2002; Choudhary et al., 2009). Lycopene scavenges free radicals at cellular level due to its attachment in cell membrane thereby may prevent hypercholesterolemia and hyperglycemia along with allied dysfunctions (Marinova et al., 2005; Fisher and Frazee, 2006).

METHODS

Narrative review method was adopted and used to explore the potential health impacts of phytochemicals present in watermelon. The research process entailed conducting a systematic search of electronic databases to identify articles on health impacts of watermelon. The articles were obtained from printed and electronic databases and used to meet the objectives of the study.

1. Prevention of high blood pressure: High blood pressure (also called hypertension) happens when your blood moves through your arteries at a higher pressure than normal. Uncontrolled high blood pressure puts you at a higher risk for stroke, heart attack, as well as heart and kidney failure. Watermelon supplements in diet can reduce aortic blood pressure and may even provide cardio protection to keep human heart healthy and working smoothly. The carotenoids present in watermelon help prevent the hardening of arteries and veins, thereby also helping reduce the risk of blood clots and atherosclerosis. Watermelon contains citrulline which helps to manage high blood pressure by aiding in nitric oxide production in the body. Watermelon fruit is also a good source of potassium. Potassium is an important component of cell and body fluids that helps controlling heart rate and blood pressure. Thus, it prevents against stroke and coronary heart diseases (Le et al., 2005).

There are several studies on changes in blood pressure readings when people consume extracts from watermelon. Figueroa et. al. (2012) while studying obese adults with prehypertension or hypertension found that when people ate watermelon extract, their ankle and brachial systolic blood pressure, diastolic blood pressure, and mean arterial pressure were significantly reduced. In similar study on postmenopausal women with hypertension, Figueroa et. al. (2013) observed reduced aortic blood pressure readings and reduced stiffness in the arteries when watermelon extract was consumed. According to Davis et al. (2015) watermelon is rich in citrulline, which is an amino acid that is converted to arginine in the body. Citrulline and arginine help in the production of nitric oxide, which is a vasodilator, it helps relax and dilate blood vessels. When the vessels are dilated, more blood can pass freely through, leading to lower blood pressure and less of a risk for such things as stroke and cardiac infarctions; the carotenoids present in watermelon help prevent the hardening of arteries and veins, thereby also helping reduce the risk of blood clots and atherosclerosis. Watermelon extracts help to reduce hypertension and lower blood pressure in obese adults.

Nutrient	Amount in 1 cup watermelon	Daily adult requirement
Energy (calories)	46.2	1,800 – 3,000
Carbohydrate (g)	11.6, including 9.6 g of sugar	130
Fiber (g)	0.6	22.4 – 33.6
Calcium (millgrams [mg])	10.8	1,000 – 1,200
Phosphorus (mg)	16.9	700
Magnesium (mg)	15.4	320 – 420
Potassium (mg)	172	4,700
Vitamin C (mg)	12.5	75 – 90
Folate (mcg, DFE)	4.6	400
Choline (mg)	6.3	425 – 550
Vitamin A, RAE (mcg)	43.1	700 – 900
Beta carotene (mcg)	467	No data
Lutein & zeaxanthin (mcg)	12.3 mcg	No data
Lycopene (mcg)	6,980	No data
Phytosterols (mg)	3.08	No data

2. Prevention of kidney disorders: Watermelon is a natural diuretic which helps increase the flow of urine, but does not strain the kidneys. Watermelon helps in liver process ammonia (waste from protein digestion) which eases strain on the kidneys while getting rid of excess fluids. Just as drinking several glasses of water is beneficial, Watermelon's high water content induces frequent urination, which, once again, is always helpful in cleansing the kidneys and keeping them functioning properly. Watermelon will provide you with an ample amount of hydration while also adding a sweet taste and delicious texture (Davis et al., 2015).

Kidney disease is one of the lifestyle conditions that affect several people around the world. Furthermore, the disease can increase the risk of other chronic disorders and make it difficult for patients to live a healthy and active life (Wayan, 2020). One of the fruits that are considered to be a source of important minerals and nutrients that can help improve kidney function and health is watermelon (Ijah et al., 2015; Choudhary et al., 2015; Naz et al., 2014; Romdhane et al., 2017). In fact, watermelons actually have a very abundant supply of both calcium and potassium, each of which contributes to helping flush out the toxins in the body's kidneys (Dogukan and Tuzcu, 2011). Even better, the calcium provided by watermelon is important for regulating cell functions, maintaining cell structure, and benefitting the cell differentiation process. Extra calcium also aids in reducing the concentration of uric acid in the blood. Too much uric acid can cause hyperuricemia, which will make you very sick. By decreasing any extra amounts of this acid, the calcium and potassium in watermelon help to reduce the chances of kidney diseases. Although these two compounds are very important, we cannot forget about water, the namesake of this beneficial fruit (Butt et al., 2009).

Epidemiological research shows that the chemicals in the watermelon have antioxidant, anti-inflammatory, and antihypertensive properties that protect against radical ions that can worsen the symptoms of kidney diseases (Kim et al., 2014; Naz et al., 2014; Romdhane et al., 2017). Siddiqui et al. (2018) recorded reduced calcium oxalate (CaOX) crystal count following the treatment with the watermelon extracts. The reduction was witnessed both in the urine and kidney samples. They also observed that the pulp extracts that were used in the *in vivo* experiments led to an increase in urinary output and pH while also preventing weight loss. Atlas et al. (2011) reported that the administration of CCL, together with watermelon extracts, reduced the level of lipid peroxide in the brain, liver, and kidney tissues. The authors concluded that the watermelon juice samples had a protective effect on the tissues that were examined.

3. Prevention of cancer: Watermelon is a good source of vitamin c, beta carotene and lycopene, a phytochemical with antioxidant activity that may protect against cancer. Some studies have also linked lycopene intake with a lower risk of prostate cancer. Scientific researches proved that watermelon have antioxidant properties, as such it may be helpful in reducing the risk of cancer. According to the National Cancer Institute, Lycopene helps in reducing prostate cancer cell proliferation. Consumption of natural fruits rich in Vitamin-A is known to protect from lung and oral cavity cancers (Reetu and Tomar, 2017). The health benefits of lycopene might extend beyond fighting prostate cancer. Accumulating evidence suggests that the anti-proliferative properties of lycopene may extend to other types of cancer (Giovannucci, 1999).

CONCLUSION

Humans cannot synthesize carotenoids and must attain these micronutrients exclusively through their diets. The consumption of Lycopene, a carotenoid that lacks Pro-Vitamin A activity, have been shown to be associated with decreased risk of chronic diseases such as cancer and cardiovascular diseases in several recent studies. Many have attributed the health benefits of lycopene to its antioxidant properties. Researches revealed presence of appreciable quantity of lycopene in watermelon. There is a need to create awareness for watermelon cultivation and consumption considering that it is highly nutritious, health promoting, easy to cultivate and produce stable yields, even under difficult climatic and edaphic conditions. However, there is still the need for more research for better understanding of role of lycopene on human health.

ABSTRACT

Ensuring food, nutritional and health security in Nigeria and other groups of developed, developing and underdeveloped nations has remained a world widespread challenge especially at these era of unstable government policy implementation, impact of climate change, Phytophthora leaf blight epidemic of taro and COVID-19 pandemic on food production irrespective of high teaming population. In the effort of ensuring nutritional, health security and better livelihood status, the underutilized, less exploited and neglected food crop and other food based product(s) should get a deserved attention. Colocasia esculenta (common name: cocoyam) popularly referred to as Ede ofe in the Southeastern States of Nigeria is an important herbaceous underground starch-rich tropical tuber food crop. It is the third most important root and tuber crops after cassava and yam in Nigeria and fourteenth vegetable crop worldwide. Its production and consumption systems, research grant, extension services and socio-economic values are not given a due attention in spite of its nutritional and health benefits. The neglect of Colocasia spp as a notable food source was as a result of inadequate knowledge and unrecognized value of its nutritional and health benefits compared to other popularly known food and medicinal crops. Therefore, there is a need to review nutritional and health status of Colocasia spp. which is a product of many research works, workshops, and experiences from many low, medium, and high income resource consumers of Ede ofe.

Key words: Ede ofe, *Colocasia esculenta*, Potential, Nutritional, Health security.

INTRODUCTION

The challenges of food security have been a serious order of the day among all classes of economic development worldwide especially at these period of poor government policy implementation, impact of climate change and COVID -19 pandemic on food production. Food provides not only essential nutrients needed for life, but also other minerals, vitamins and phytochemical compounds for health promotion and disease prevention. The promotion and consumption of underutilized food crop like *Colocasia esculenta* (taro, cocoyam) could help to mitigate food insecurity and alleviate malnutrition in underdeveloped, developing and developed nations. Traditional vegetables, which cocoyam tubers, petioles, leaves and flowers are inclusive, are valuable sources of nutrients (Nesamvuni et al., 2001; Yang and Keding, 2009) with some having important medicinal properties (Hilou et al*.,* 2006). Vegetables contribute substantially to food security (Yiridoe and Anchirinah, 2005). Overcoming food, nutritional and health insecurity among all classes of humans such as women, children, pregnant and lactating mothers, remains a challenge in many developing countries in Sub-Sahara African nations (Andersen *et al.,* 2003), including all classes of poor and rich income resources families.

Ede ofe (*Colocasia spp.*) is an important edible underground starch-rich food crop cultivated in upland or wetland of tropical and sub-tropical regions. It is the third most important starch tuber crop after cassava and yam in Nigeria; second and first in Ghana and Cameroon, respectively and fourteenth vegetable crop worldwide (Brooks, 2012). *Colocasia spp.* is a unique and giant crop because all parts (tubers, stems, leaves and flowers) are good sources of carbohydrate, protein, minerals, vitamins and phytochemical compounds. However, the neglect of

Colocasia spp. might be due to poor knowledge and less popularization of its nutritional and health advantages both for low, medium and high income resources families. The nutritional and health status popularization of cocoyam diet deserved full attention at the recent period of high rate of malnutrition, due to high intake of processed and packaged food materials and as well as a lot of diseases related to poor intake of rich diet like *Colocasia spp.*

NUTRITIONAL AND HEALTH STATUS OF EDE OFE

Nutritionally, as food for humans and livestock consumption and also source of agro-based industrial raw materials for mankind, the value of cocoyam parts is caloric (Davies et al., 2008). Cocoyam is superior to cassava and yam because of its high protein contents, minerals, vitamins and as well high digestible starch (Onyenweaku and Okoye, 2007). The nutritional content of cocoyam tuber like other root and tuber crops is low in protein and fat, but high in the starch and also good source of minerals. The consumption of nutrient rich foods like cocoyam helps the body to utilize protein, carbohydrates and other nutrients (Njoku and Ohia, 2007).

Starch: Cocoyam tuber has been reported to have high (70 - 88%) carbohydrate on dry weight basis mainly in the form of starch (Bradbury and Holloway, 1988; Onwueme and Charles,1994). The carbohydrate content of cocoyam not only impart desirable functional property to foods, but also provides high energy value and promotes satiety to consumers (Owusu-Darko et al.*,)*, granule size (1-4μm) in diameter of its starch which vary with cultivars. Cocoyam starch is highly gluten free (Rekha and Padmaja, 2002), and contains about 50% less amylose and amylopectin content which is higher compared to cereals. The amylose/amylopetin ratio is 1:7. The most important sugar content in cocoyam is sucrose and small quantities of fructose, maltose, glucose and raffinose. The most important organic acids are malic acid (60%), followed by citric acid (25%) and oxalic acid (15%) (Arnavid-vinas and Lorenz,1999). In view of cocoyam small starch granule size, it aids easy digestion, improves bowel movement, absorption and as well prevents constipation. It has also been used for industrial purposes (Uguru, 2011) like alcohol production (breweries), baby foods, cocoyam bread, biscuits, plastics, paste, cosmetics etc. The easily digestible small starch granule size are used by diabetics, weaning children, aged people, people with allergic gastro intestinal stomach disorder, obesity, cancer (Opara, 2002, Dimelu et al., 2009; Uguru, 2011); peptic ulcer patients, patients with pancreatic diseases, chronic liver problem, inflammatory bowel disease like pile and gall bladder disease (Emmanuel-Ikpeme, et al., 2007), stroke and obesity patients due to its low glycemic index or hypo allergenic nature (low tendency to cause reaction). Also, its low glycemic index makes it an excellent food for diabetics, who require glucose to be released into their bloodstream slowly. Cocoyam small granule starch size can also be used for the treatment of cough, wound, sore throat, ringworms (Chatterjee and Pakrashi, 2011; Kirtikar and Bassua, 2001), mild laxative, snake bite and high body temperature in Malaysia (Ofu,1994) and swollen joints in Nsukka area.

Protein and amino acid: Cocoyam tuber has been known to contain 10.8 - 11% crude protein on dry weight basis (Chinnasarn and Manyasi, 2010. This protein value is more than yam (7:4%), cassava (4.5%) and sweet potato (8.5%) (Jane et al.,1992). It was observed that protein content of cocoyam tuber is more towards periphery than toward its centre, which suggest that care should be taken when peeling cocoyam tuber, otherwise a large amount of protein could be lost in the peeling processes (Mbofung et al., 2006). On cocoyam leaves, it contains high protein (23%) on a dry weight basis (Onwueme, 1994; FAO, 1999) which is rich compared to other root and tuber crops. The protein content is rich in essential amino acids of threonine, argnine, leucine, valine and phenylalanine. The methionine, leucine, lycine, throenine and phenylalanine are more in the leaf than the tubers. Cocoyam tubers contain higher amount of threonine leuice, argaine, valine and phenylalanine. Sulphur containing amino acid is limiting (Mwenye et al., 2011).

Moisture: Moisture content of cocoyam is very high and records about two third (>70%) and ranges from 60 – 83 % of the total weight of fresh crops (FAO, 1999; Huany et al., 2007. Moisture content of cocoyam varies with cultivars, time of harvesting, growth environment and storage conditions. The high moisture content of cocoyam is associated with high rate of spoilage (rots) after harvest and during storage by myco-induced rot pathogens.

Minerals: Cocoyam tubers and leaves are rich in minerals with potassium recording the highest followed by phosphorus (Olayiwola et al., 2012; Ukpong et al., 2014) and next by calcium. The other important minerals include iron, copper, sodium, manganese, magnesium (Abbo et al., 2000; Onyeka, 2014). The potassium rich diet like cocoyam is essential for osmotic pressure regulation in the body. It helps to promote the excretion of excess sodium ions in the body, improve eye functioning, and maintains water and sodium balance in the body. Phosphorus in cocoyam is required by every cell in the body for normal functioning, male fertility and reproduction. Calciun in conjunction with phosphorus, potassium and magnesium improves skeletal structure of bone and teeth formation. The calcium fraction of cocoyam is located in the skin (Abbo et al., 2000) and the consumption of non-peeled boiled tuber would be helpful in calcium deficient diet. Magnesium in cocoyam decreases inflammation in blood vessels, increase blood flow. It also boosts men's sexual urge (arousal) and make sex more pleasurable and as well make men erection to perform more naturally. Cocoyam diet can also boost testerone in the body system. Potassium and magnesium rich diets promote heart health. Cocoyam contains high levels of iron (10.4mg/100) compared to other root and tuber crops. Iron is a useful micronutrient for haemoglobin building, normal functioning of central nervous system and in the oxidation of carbohydrate, protein, and fats. (Mlitan et al*.,* 2014). It facilitates carbohydrate, protein, and fat to control body weight which is very essential factor in diabetes (Moses et al*.,* 2012). Iron is essential for oxygen transfer in human and low iron content in diet causes gastrointestinal infection, nose bleeding, myocardial infection (Ulla et al., 2012). Iron rich diets are a cure to anaemia. Zinc is an essential microelement that plays an important role in various cell processes such as brain development, normal growth behavioral response, bone formation, and wound healing (Mlitan et al., 2014). Zinc promote protein and carbohydrate metabolism and also help in mobilizing Vitamin A in the liver and as well enhance the synthesis of DNA and RNA necessary for cell formation (Jabeen et al*.,* 2010). Zinc deficiency symptom is common in people suffering from Chrohn's disease, hypothyroidism and gum disease and probably plays a role in susceptibility to viral infection and diabetes mellitus. Zinc play a good role in the treatment of viral infection including AID patients, prostate gland enlargement, rheumatoid arthritis, wound healing, acne eczema and stress (Ker manshah et al., 2014), promotes normal fertility and reproduction. The minerals content of cocoyam varies among cultivars especially between the green and purple cultivars as observed by Olayiwola (2012) and Ukpong *et al.,* (2014). The mineral variation may be attributed to growth environment, soil types, and genotype and other cultural practices applied like manuring/fertilization types and rates. In general, cocoyam parts contain a lot of minerals which their salts are used as a regulator of acid - base balance of the body (Njoku and Ohia, 2007, Niba, 2013). The micronutrient in cocoyam help in building strong immune system, thereby helping the body to digest, absorb and utilize nutrients (Muinat *et al.,* 2009)

Cocoyam dietary fibers: Cocoyam diet is rich in fiber. Cocoyam diets contain (dry matter basis) high dietary fibers ranging from 1.28 - 5% (Chinnasarrn and Manyasi, 2010; Matikiti, 2017). The high dietary content of cocoyam parts plays active role in the regulation of intestinal transit, increasing dietary bulk and faeces consistency due to their ability to absorb water (Singh et al*.,* 2012); Abujah et al., 2015). Dietary fiber (non - carbohydrate) promote the growth and protects the beneficial intestinal flora. Further, high intake of dietary fiber diet reduces the risk of colon cancer (Dar zynski et al., 2007). Fiber rich diets help to lower cholesterol and reduce constipation. However, low fiber is unhealthy, as it can cause constipation resulting in disease of the colon like pile, appendices and cancer (Olalege et al*.,* 2013)

Cocoyam crude fat/ lipid: Cocoyam is a low fat crop. Dietary fats promote the palatability of food by absorbing and retaining flavors (Antia et al., 2006).

Consumption of excess fats have been implicated in certain cardiovascular disorders such as anthrsclerois, cancer, aging, whereas a diet supplying less than 2 % of caloric energy as fat is said to be good for human (Arua et al., 2011). In general, the crude fat content of cocoyam range from 0.20 – 1.10% (Chinnasarn and Manyasi, 2010; Mitikiti, 2017) and varies among cultivars.

Vitamins: Cocoyam parts especially the leaves, petioles and flowers are rich in vitamins such as vitamin A and C, thiamine (B_1), riboflavin (B_2), niacin (B_3) (FAO,1993; Barua,2002). The Vitamin C rich diet, like cocoyam, is a key for immune system support, fighting free radicals, anti-heart diseases and eye health. Vitamin C supports overall brain health and prevents brain cells from becoming damaged. Thiamin (Vitamin B_1) rich diet like cocoyam taro is necessary in our modern daily feeding systems where a lot of refined starch is eaten (Parkison, 1984 Ezedinma, 2006). Cocoyam rich in Vitamin B_1 is required for normal growth, proper functioning of the heart and nervous system. B_6 (niacin) vitamin is needed for cellular respiration. The niacin, thiamin and riboflavin in cocoyam diet help the body cells to regenerate and form new tissues. The boiled cocoyam leaf contains beta-carotene (996 g/100g), iron (12mg/100g, ascorbic acid 87mg/100g (FAO, 1990; Jirarat et al., 2006). Cocoyam with yellow fleshed tuber contains more levels of beta - carotene than white fleshed tuber cultivar type/genotype. High levels of beta-carotene support vitamin A formation (pro - vitamin A production) which is essential for a healthy immune system that promote good eye, bone formation. Food rich in carotenoids have been shown to protect body against chronic diseases like heart disease, cancer, cardiovascular disease, diabetes etc. (Engilberger et al.,2003; Uguru, 2011).

Ash contents: Ash content value is a measure or reflection of the nutritionally important mineral contents present in the food materials (Omotosho, 2005); Nnamani et al., 2009). It helps to determine the much and type of minerals in cocoyam as minerals are essential for growth and metabolism in humans and helps to reduce mineral deficiency disease like cancer, goiter, crenistism and mycardiopathy and also reducing the risk of contracting other chronic diseases like cancer and cardiovascular (Wiesler et al*.,* 2010). The ash content of cocoyam ranges from 3 -5% as reported by many literatures (Chinnasarn and Manyasi, 2010; Lewu et al., 2010).

Total energy value (Kcal/100g): Energy content of any diet is associated with its carbohydrate content (higher energy value more carbohydrate content). Gross energy value varies among cocoyam cultivars. It has been reported that the gross energy (kcal/100) of cocoyam cultivar ranged from 380.27 in purple cocoyam, 378.47 in green cocoyam and 370 - 374 kcal/100g in Boloso 1 from Ethiopia (Adane et al., 2013). This explains why purple type (Nce 002/Nachi) in Nsukka region commands high demand/cost compared to other cultivars in soup, flaked and other cocoyam based products formulations/recipes and health applications. Phytochemically, *Colocasia spp.* has been known to possess many bioactive compounds that have biological and pharmaceutical benefits. Cocoyam taro has been reported to possess some valuable natural compounds that are health promoting materials which include antioxidants and phytochemicals. Antioxidants are substances that delay, prevent, or remove oxidative damage to some target molecules (Haliwell and Guteridge,1998), which prevent damage to cellular components arising as a result of chemical reactions involving free radicals (Prochazkova et al., 2011), prevent skin from aging, maintain and balance hormone. Antioxidants help to strengthen the body's immunity to disease and infection. Farombi et al. (1998) observed that phytochemicals are effective in combating or preventing diseases due to their antioxidant properties. These antioxidants protect biological systems and molecules from oxidation when they are exposed to free radicals and reactive oxygen species which have been implicated in the aetiology of many diseases, food deterioration and storage (Farombi, 2000).

Natural Compound Contents of Cocoyam

The biological properties of cocoyam were attributed to the natural compound contents in it such as:

Tannins: Tannins are natural occurring substances in taro plant that could be partly responsible for the bitter taste associated with the raw flowers and its use in

ISSN: 2814-0508

wound treatment. Tannin possess astringent properties, that speed up the healing of wounds and inflamed mucous membrane (Okwu and Okwu, 2004). Tannins are water soluble high molecular weight phenolic compounds in any plants that are valuable in herbal medicine due to their wound healing properties (Nguyi, 1988). They also possess fungicidal properties, thereby serving as a defense mechanism in plants against herbivores, pathogens and hostile environment. However, Tannin content of cocoyam have been shown to interact with proteins, enzymes or no enzymes and form tannin protein complexes that can reduce protein digestibility and protein solubility. Reduction of protein digestibility could be attributed to either the inactivation of digestive enzymes or reduction of the susceptibility of the protein substrates after forming complex. Tannin also decreased the bioavailability of Vitamins A, B, C and some minerals like Zn, Fe, I, P and Mg (Chavan et al., 1986). The removal of tuber skins (peeling) and cooking can considerably reduce certain amount of tannins.

Beta-carotene: Beta- carotene is an essential substance among yellow fleshed cocoyam tubers and leaves that promotes vitamin A production. High amount of β-carotene in cocoyam tubers and leaves (96 ug/00g) will impart vitamin A and antioxidant in the body (Agwunobi et al., 2012). Beta-carotenes are commonly carotenoids of β and α - carotenes and antioxidants as well as possessing other potential health benefits. As earlier reported, carotenoids can be convertible into vitamin A by the body. Beta-carotene is most A activity of the carotenoids and are used against cataracts and lung cancers (Gallicchio et al., 2008).

Polyphenolic compounds: Phenolic compounds are phenolic acid of phosphorus that is widely distributed in the plant cell walls and as well a significant composition of human diets. Pheolic acids and flavonoids are known to possess antioxidants properties due to presence of hydroxyl in their structures and their redox properties (Zahid et al., 2015). Pale fleshed cocoyam cultivar is associated with a high level of total phenolic compounds than white fleshed cocoyam cultivar (Wolfe et al., 2007).

Alkaloids: Alkaloids are colourless, but are often optically active materials with bitter tastes e.g. alkaloid quinine. Alkaloids are mostly crystalline, but a few are liquid at room temperature. Alkaloids are mainly natural products occurring primarily in many plants. They rank among the most efficient and therapeutically significant plant substance (Okwu, 2005). Alkaloids are naturally occurring compound with pharmaceutical properties that are used as medication, as recreational drugs for local anesthetic and stimulant cocaine, nicotine, the analgesic morphine or anti-malarial drug quinine (Kam and Liew, 2002), spasmodial and bactericidal (Edoga and Eriata, 2001). Over 5,500 alkaloids like quinines, codeine, heroin, diterpanoid, berberine, glycol, harmane etc are known and they comprise the largest single class of secondary plant materials which contain one or more nitrogen atoms usually in combination as a part of cyclic structure. Alkaloids, comprising a large group of nitrogenous compound are widely used as therapeutic agents in the management of cancer. Alkaloids exhibit a marked physiological activity when administered to animals (Okwu and Okwu, 2004). Alkaloids interfere with cell division and are generally found in the form of salts with organic acids and they are also haemolytically active and as well toxic to pathogenic organisms. Some alkaloids are commonly found to have anti-microbial properties and are useful against HIV infection as well as intestinal infection associated with AIDS (Edoga and Eriata, 2001). Alkaloids acts directly on the vascular systems and also exerts a number of effect on the neural tissues and thus, indirectly affect the mechanical and electrical activities of the heart and modify vascular resistance and capacitance. Alkaloids are contained in cocoyam in moderate quantity (Ukpong et al., 2014).

Flavonoids: Flavonoids are basically a class of secondary metabolites widely distribute in plants, fruits, leaves and flowers. They are 15- carbon compounds generally distributed throughout the plant kingdom. Flavonoids are synthesized by plants in response to microbial infection and as well found *in vitro* to be effective against a wide range of pathogenic organisms. Flavonoids like anthogenina give colour to flowers, fruit and leaves in plants. The presence of flavonoids testified the possession of medicinal properties by plant leaves. Flavonoids are free radicals, scavengers, excellent antioxidant and potent water soluble compounds that prevent oxidative cell damage and have a promising anti-cancer activity (Onwueyiagba, 2001). It has been reported by that flavonoids have antiviral, anti-allergic, anti-inflammatory, anticancer and antioxidant properties. The antioxidant property and subsequent inhibition of low-density lipo have been attributed to the dietary and supplemental intake of flavonoids and other trace nutrients. Flavonoids have a significant therapeutic action and form the ingredient of many important drugs. Flavonoids help to reduce cholesterol and respiratory related problems to breath well and easily in the body. Flavonoids as the largest group of phenolics recorded in fruits, vegetables and other plant parts have been associated with the reduction of major degenerative diseases (Liu, 2003). Flavonoids are found in varying quantities in foods and medicinal plants due to its potent antioxidant property against the superoxide radicals. Ukpong *et al.,*2014) reported that cocoyam contains flavonoids in moderate quantity.

Saponins: Saponins are naturally occurring in plants that are useful in medicines and pharmaceutical industries due to its foaming potential for the production of vaccines, insecticides and synthesis of steroidal hormones. Studies have shown that saponins have a strong potential to reduce cholesterol levels in man and animals. However, Ukpong et al. (2014) reported that saponins are found in minor quantity among the photochemical components of cocoyam.

Terpene: Terpene, also known as plant terpenoids, are reported to play a role in traditional herbal medicine as pharmaceutical purposes. Ukpony et al. (2014) in their photochemical studies and mineral contents of cocoyam reported that cocoyam contained terpenoids in high quantity.

Cardiac glycosides: Cardiac glycosides are naturally occurring drug materials in plants known drugs materials in plant known for their beneficial and toxic activity on the heart. As an active ingredient in many promising heart drugs, it is used therapeutically in the treatment of disease related to heart problem like cardiac failure (Trease and Evans, 1989). Cardiac glycosides were reported to be in high quantity in cocoyam (Ukpong et al., 2014). Generally, the bioactive compounds of cocoyam, medically exhibits a lot of biological functions such as immune-stimulatory, anti-inflammatory, antimicrobial activities, anemiagenic, 5- α- reductase inhibitory, anti-tumor, α-reductase inhibitory, anti-leucotriene-D4, anti-androgenic, lipoxygenase inhibitory, anti-alopecic, inhibition of prostate and breast cancer cell lines, anti-helminthic, prospective anti prostatic and hypocholesterolemic properties in the body (Kundu et al*.,* 2012; Omotoso et al., 2014; Eleazu et al., 2016; Eleazu, 2016; Orji, 2019),), anti-mestatic activity by inhibiting the proliferation of some breast and prostate cancer cell lines (Kundu et al*.,* 2012), anti-secretory, contraceptive, choleretic, anti-spermatogenic and anti-tubercular properties (Kalaivani et al., 2012; Eleazu et al., 2016), antiradical, anti-mutagenic and antoxidant potentials (Ryszad,2007), antibacterial and antifungal properties (Karikalan and Rajangam,2014). These therapeutic properties are linked to the presence of one or more of the natural compounds as shown in Table 1.

However, cocoyam contains anti-nutrients in the food materials that act against one or more nutrients, reducing digestibility and bioavailability. The dietary minerals mostly affected include zinc, iron, calcium, magnesium, manganese and copper (Lopex et al*.,* 2002; Sarkiyayi and Agar, 2010). This is usually formed through complex processes, which reduces nutrient absorption (Dumont and Veruier, 2000) and utilization. Ukpong et al. 2014 observed that anti-nutrients of cocoyam have negative effects for cocoyam as food and as well have positive implications for cocoyam as crop that can be grown with less use of fungicides and pesticides especially in the wild taro. The anti-nutrients mainly found in cocoyam include mucilage, calcium raphide (oxalate), phytate, alpha amylase inhibitors, protease inhibitors (Ramanatha et al., 2010).

Phytate: Phytate, also referred to as phytate phosphorus, is a phosphorus containing substance that binds with minerals and reduce mineral absorption and utilization. It is also a storage form of phosphorus occurring in plants seeds and many roots and tubers (Dipak and Mukherje, 1986). The reduced mineral absorption associated with the presence of negatively charged phosphate groups that form very stable complexes with mineral ions causing non-availability for intestinal absorption (Walter et al., 2002). The dietary minerals mostly affected include zinc, iron, calcium, magnesium, manganese and copper (Lopex et al., 2002; Sarkiyayi and Agar, 2010). Phytate can also form complexes with proteins, protease and amylase of the intestinal tract therefore, reducing proteolysis**.** The phytate content in crop depends on growth conditions, soil types, season, cultivars, manuring/fertilization types and rates. Sarkiyayi and Agar, (2010) reported that both green and purple cocoyam cultivars significantly recorded high phytate quantities, but higher in purple cocoyam (187.57 mg/100g) than the green cocoyam (167mg/100g). In cocoyam, most of the anti-nutrients are partly or totally water soluble and can be significantly reduced by processing methods such as cooking, boiling, fermentation, pre-drying, deep in hot or cold water, blanching, roasting (Frias et al., 2000, Adane et al., 2013; Aneze and Molla, 2017).

Table1. Natural compounds of *Colocasia esculenta* L.

Name of compound	Molecular formula.	Molecular weight	% Content
Hexadecanoic acid methyl	$C_{17}H_{34}O_2$	270	0.43
Octadecanoic acid	$C_{18}H_{36}O_2$	284	20.91
9,12-Octadecadienoyl chloride	$C_{18}H_{31}ClO$	298	0.77
11-Octadecenoic acid methyl ester	$C_{19}H_{36}O_2$	296	2.12
9-Octadecenoic acid	$C_{18}H_{34}O_2$	282	64.37
4-Methylimidazolium ion	$C_{24}H_{45}N_2O_3$	409	1.36
Hexanedioic acid 2-ethylhexy ester	$C_{22}H_{42}O_4$	370	1.36
3,5-Di-*t*-butyl phenol 0	$C_4H_{22}O$	206	3.27

Source: Eleazu, 2016.

Oxalate: Oxalate is a chemical substance in cocoyam that imparts acrid taste or cause irritation on exposed skin during processing or in the throat and mouth epithelium especially for the less boiled cocoyam on ingestion (Akpa and Umoh, 2014) and indirectly affecting the eating value and digestibility. It is one of the major factors limiting the utilization of cocoyam. The acridity of cocoyam diet is caused by needle like calcium crystals, raphides that can penetrate soft tissues or skin (Bradbury and Nixon, 2008). The raphides may be a protease can cause discomfort in the tissue (Bradbury and Nixon, 1998). High amount (2856 mg/100g), oxalic acid is toxic to humans and can also reduce the nutritional quality of cocoyam by binding with calcium to form calcium oxalate (Hany et al., 2011). All parts of cocoyam cultivars were known to contain calcium oxalate which is destroyed by lengthy cooking (Hedyes and Lister, 2006). Studies showed that boiling cocoyam at the 90^{o}C for 30 minutes, and steeping in water at 30^{o}c for 24 hours can reduce the oxalate salt content of 32.7% and 56.7% of its original content, respectively (Iwuoha and Kalu, 1994). Also, the calcium oxalate content in cocoyam leaves can also be reduced by sun-drying and storing (Emmans, 2008). Studies on different methods of processing cocoyam tubers and leaves like boiling, fermentation, drying, cooking methods etc have shown a great effect in reducing the level of oxalate, tannin, all nutrients inhibitors, phytate and as well improve the nutrient contents of cocoyam (Malavanah *et al.,* 2008b). Further, the consumption of adequate diary or calcium based food in taro diet like milk and milk products has been reported to reduce the acridity of taro caused by calcum oxalate (Munait et al.,2009). The adequate intake of calcium together with spinach, an oxalate rich diet will help to reduce the uptake of oxalate (Brogren and Savage, 2003).

Cocoyam mucilage: Cocoyam mucilage is a slimy material like nasal discharge coming out from the raw

ISSN: 2814-0508

cocoyam tubers or leaves when the fresh surface is cut into pieces or exposed fresh surface. Mucilage also occurs on boiled cocoyam tubers during processing for flakes. The great quantity of mucilage is removed or reduced when the pieces of cocoyam tuber are washed or placed in water (Nipp, 1997). Mucilage can also be eliminated by discarding the water used for cooking or the tubers can be cooked without water or roasted (fried or baked) in order to have a partial dehydration or dry texture. However, taro mucilage has a health benefits by aiding digestibility and slower blood glucose, slow transit of food through the upper gastro-intestinal tract, water absorption and retain moisture that reduce constipation (Njintany et al., 2011).

Protease inhibitors: Protease inhibitor also known as trysin or chymotrypsin is another causal factor of acridity from eating raw or partially cooked cocoyam parts (Bradhury et al*.,* 2008) including the poorly sun dried or boiled leaves. The acridity in the cocoyam tubers and leaves are experienced as a severe itching, stinging or burning sensation in the mouth and throat followed by swelling or as a less severe irritation or itching of external tissues (Osisiogu et al., 1994). The trypsin inhibitors constitute about 1- 4% of the total protein in tubers and are absent or inert in leaves. The twenty minute of boiling is reported to remove trypsin activity adequately and also enough to remove the acidity in many cocoyam cultivars (Bradbury and Holloway, 1988; Bradbury and Hammer, 1990).

Alpha-amylase inhibitors: Alpha-amylase inhibitors are digestive enzymes of the starch in man and animals. They are in saliva and the small intestines and can be inhibited by specific enzymes from many plants. Alpha - amylase inhibitors in cocoyam parts can inactivate human salivary and pancreatic amylases (Mace and Godwin, 2002). However, alpha –amylase inhibitors are not resistant to heat and can be deactivated by usual cooking practices.

CONCLUSION AND RECOMMENDATIONS

The nutritional and health values of a diet should be a main concern when a crop is being considered as food source. Food is one of the necessities of life for good nutritional and health security. Enough consumption of Ede ofe is an indirect way of dealing with medicinal plants which is a cornerstone of traditional practices of nutritional and health care. "You are what you consume" is a very unique saying because the food we eat plays a crucial role in our daily wellbeing. The most recent silent killer and degenerative diseases known today has been associated with our diets. Prevention is the better than cure, they say. Therefore, it is very essential that we check what we eat and as well to start to re-think the nutritional and health benefits of those neglected food crops like *Colocasia spp*. *Colocasia spp.* diet is an excellent way of ensuring that our body is well supplied with the outstanding and essential phyto-nutrients it needs to meet the demand of healthy and balanced lifestyle. Cocoyam products are locally sourced and should be included in daily feeding schedules in any form of formulation like pounded as fufu, or mixed/pounded together with either cassava, yam, garri or plantain as food softener, taro chip (achicha) with *Cajanus cajan* or black beans (Akidi) and other available ingredients.

ABSTRACT

The dangers of malnutrition pose serious health issues like cardiovascular diseases, diabetes, cancer, and stunted growth. The rate of increase in malnutrition amongst mothers and children during and after birth is significantly high, both in rural and urban Lagos State metropolis. The study evaluates cashew kernel consumption as a food supplement to curb malnutrition status in Lagos state metropolis. Information on socio-economic characteristics, macronutrients and micronutrients consumption of food nutrients by 90 respondents from three Local Government Areas: Ojo, Ikeja and Isolo were collected. The respondents were selected using simple random sampling technique with the aid of interview schedules and questionnaires administered on consumers who were 18 years and above, about 50% of self-employed. The mean age and family size of respondents is approximately 35 years and 6people respectively. The nutrient consumption revealed that macronutrients {carbohydrate (93.3%), protein (87.8%), and fat (55.7%)} were consumed more frequently than micronutrients which includes vitamins and minerals nutrients; groundnut (67.8 %), cashew nut (59%), peanuts (31.1%), and coconut (28.9) as favorite snacks respectively. The study also identified higher percent of respondents that could can spent above ₦1500 weekly on cashew nut kernel (1kg bottle size) as their favorite snack, compared with those that could afford it. Chi-square results revealed that marital (x^2=60.048, educational status x^2=42.341, and occupation (x^2=25.227, at $p\leq0.05$) were significantly related to cashew kernel consumption among respondents which implies that the aforementioned variables has positive influence on cashew kernel consumption in the study area. The dominance of macronutrients from the study shows imbalance in the daily food consumption of the respondents. The use of cashew kernel as supplement to malnutrition status was underutilized due to indicated factors faced by consumers. It is advisable that cashew kernel consumption be encouraged to be part of daily meal of families residing in Lagos State and beyond. Government establishment of polices that will encourage the production, processing and consumption of cashew nut kernel by subsidizing the cost of the production, through farm input mechanization, will trigger the rate of consumption, at an affordable price to meet with nutrients needed for balanced diet.

Key words: Malnutrition, cashew consumption, food nutrients, Lagos State.

INTRODUCTION

Cashew nut (*Anacardium occidentale*) is an economic nut tree that belongs to the family Anacardiaceae. It originated from Brazil, first introduced in Nigeria 15th century ago by Portuguese explorers as horticulture. Presently, it is domesticated in Africa, South America and Asia as a source of food, industrial raw materials and foreign exchange to many countries. Cashew nut is produced in many parts of Nigeria, but predominantly in the southern and middle belt region. Cashew kernel is the real fruit embedded inside the shell of cashew nut. It has two distinct kidney shape parts and its color varies from lite green (fresh kernel) to grayish brown (dried kernel). According to Kluczkovski (2016) about 20–25% of the cashew kernel occupied the total cashew nut, wrapped in a thin, difficult to remove peel reddish-brown membrane. Cashew kernel popularity began right from early school days, in the lives of respondents not only because it has a nice smell, with buttery flavor, but also because they are loaded with vitamins and minerals needed for a balanced diet. Laura Griffin (2017) said that the nutrients obtained from cashew kernel nutrients after oil extraction contains about 45% crude protein, 2% crude fiber and 6% ash. Both nutrients are good food materials for repairing damaged tissues (supplement). It is also known that cashew kernel nutrients are rich in essential amino acids that are normally not common in plants (Ekpeyong, 1997).

The US department of Agriculture (USDA) National Nutrient Database shows that 28.35 g of cashews kernel contains 157 calories from 1.68 g of sugar, 0.9 g of fiber, 10 mg of calcium, 1.89 mg of iron, 83 mg of magnesium, 168 mg of phosphorus, 187 mg of potassium, 3 mg of sodium, 1.64 mg of zinc, 0.1 mg of ascorbic acid, 0.120 mg of thiamine, 0.016 mg of riboflavin, and 0.301 mg of niacin, 5.17 g of protein, 8.56 g of carbohydrate, 12.43 g of total fat, also contain 50% fats in form of unsaturated fats, which helps in weight management considering that it has enough calories. It is a good source of vitamin E and minerals especially magnesium and zinc, which contain vitamins C and B. (USDA, 2019)

The nutritional status in Lagos State, the most populous city in Nigeria, is acute according to national nutrition and health survey NNHS (2018). Lagos State has all it takes to set a good nutritional record as an example to other neighboring states and other West African countries to adopt, for maximum calorie needed, for a healthy society living which improves socio economic activities of the people thereby creating more wealth for the state. But the dietary patterns and the nutritional knowledge of adults, especially women and children, in Lagos State metropolis were poor; obesity and overweight are higher than previously. Obesity is a sign of malnutrition, which promotes excessive body fat and increase in weight and sets the risk of health problems. The high rate of malnutrition status in Lagos state can cause public health outbreak amongst residents of the state especially women and children (Olatona, 2020).

In 2018, the national nutrition and health survey (NNHS, 2018) concluded that the rate of malnutrition in Lagos State is at an acute level. To alleviate the problems in a developing country like Nigeria, there is a need to accept change in nutritional patterns. Foods stuffs with lots of vitamins and minerals, and a reasonable amount of carbohydrate, protein and soluble fat should be adopted. Cashew kernel has been reported to be rich in proteins and other missing minerals causing malnutrition. It is a moderate source of iron, riboflavin, thiamine and a good source of amino acid which is not common in plants (Ekpeyong, 1997). At the peak of sudden changes and challenges in the health sector due to Covid-19 pandemic outbreak among humans, Lagos state recorded the lion share of affected persons compared to other states in Nigeria. It is advisable to improve the immune system by the use of food supplements, such as cashew kernel, to fortify missing diets in meals. Although, there are several food supplements mostly from nuts, the cashew kernel is highly favored by majority over others due to its high variety of nutrients, attractive smell and buttery taste.

The main objective of this paper is to evaluate the consumption of cashew kernel as food supplement to balance malnutrition status in Lagos state metropolis. The specific objectives are to: 1) Examine the Socio economic characteristics of respondents, 2) Determine the level of cashew kernel consumption and 3) Investigate the factors facing cashew kernel consumption as a food supplement in the metropolis.

MATERIALS AND METHODS

The study was purposively carried out in Lagos State Nigeria due to the population density of the area, as one of the most populated cities in the country and West Africa region, with higher rate of socio-economic activities and opportunities. Based on that, the study of cashew kernel consumption as food supplement was fully participatory and involved 90 respondents who were 18 years and above, selected from 3 Local Governments Areas LGAs (Ojo, Ikeja, Isolo). The respondents were sampled from a document provided by the Lagos State Ministry of Health, Alausa, Ikeja. Information from the ministry categorized these LGAs as epidemic prone areas in the state. The use of questionnaire was used in getting information from consumers. Data were analyzed with descriptive and inferential statistics. The following variables were considered in the study: socio-economic characteristics of respondents, cashew kernel, macronutrients and micronutrients consumption and constraints faced by respondents in consumption of cashew kernel as food supplement in the metropolis.

ISSN: 2814-0508

RESULTS

The results on the socio-economic status of respondents are shown in table 1 below. The respondents were 56.7% female and 43.3% male indicating that female formed the major consumers. Fifty percent of the respondents had tertiary educational while 6.7% attended primary school. The civil servants were 17.8% with 50% self-employed. The cashew consumers' average family size is approximately 6 with the mean age of respondents as 35 years meaning that they were mostly young persons. The mean values for the respective macronutrients consumption revealed that carbohydrate (62.4), protein (55.7), and fat (27.6) were frequently consumed more than the required micronutrients, which contains fruits (54.04) vegetables (49.67) and nuts (43.70). The micro nutrients, which contain vitamins and minerals needed as food supplement, were consumed mostly from groundnut (82), cashew nut (81), peanuts (65), and coconut (62) by the respondents as favorite snacks, respectively (Table 2). The contributing factors that encourage low cashew nut consumption by respondent showed that 66 persons believe the price of cashew nut kernel contributed to the inadequate consumption, while 43 and 29 people believed that it was due to economic status and availability, respectively (Table 3). Chi-square results revealed that marital (x^2=60.048), educational status (x^2=42.341) and occupation (x^2=25.227, at $p \leq 0.05$) were significantly related to cashew kernel consumption among respondents. The implication of this is that these variables have influence on the consumption of cashew kernel in the study area. The educational level and occupation of respondents makes them to be more informed about the type of food nutrients they take.

DISCUSSION

The socio-economic characteristics of cashew kernel consumers in Lagos metropolis had significant relationship with cashew consumption, because most of the respondents were young and married. Despite the higher percentage of respondents that preferred cashew nut kernels as their favorite snacks, groundnut was highly chosen as substitute snacks to cashew nut kernel due to its relatively cheap and availability in all seasons. Apart from protein, other uncommon essential minerals possessed by cashew kernel over groundnut is its ability to supplement diets from monounsaturated and polyunsaturated fatty acid which helps to reduce the risk of coronary heart disease to about 37 percent (Megan, 2018). British Journal of Nutrition also confirmed that a person taking handful of cashew nuts daily have lower risk of coronary heart disease (Estruch, 2013). Although, most people indicated cashew nut as favorite snacks, yet they purchase more groundnuts than cashew nut, due to the price, availability and affordability as indicated by the respondents as their major constraints suppressing cashew nut kernel consumption in Lagos metropolis. Therefore, a well design polices to capture frequent consumption of cashew nut kernel by the government is a welcome development, thereby making cashew kernel available and affordable to create a free market for the consumers to bargain prices according to their budgets.

Field survey data, 2021 * = significant at p≤0.05

CONCLUSION AND RECOMMENDATION

The use of cashew kernel as food supplement to malnutrition status in Lagos State is underutilized, due to dominance of macronutrients consumption in the daily food items and poor supplement intake by the respondent. It is advisable that cashew kernel consumption be encouraged to be part of daily meal of families residing in Lagos State and beyond. Government should make polices that will encourage production, processing and consumption of cashew nut kernel by subsidizing the cost of production through supply of farm input to farmers at affordable prices. This will trigger the rate of consumption, at an affordable price to meet with nutrients needed for balanced diet.

ABSTRACT

Pentaclethra macrophylla is a forest tree crop that is grown as semi wild or cultivated crop especially in South Eastern and South southern Nigeria. It is a highly underutilized leguminous tree crop with high potentials for climate change mitigation, soil improvement, food security, poverty alleviation and health benefits. It is an important and cheap source of protein for people whose staple foods are deficient in proteins. It is also eaten as a delicacy and used as flavoring for soup. The seeds contain protein and minerals necessary for combating micronutrient deficiency and hidden hunger. Its seeds are processed through fermentation to remove toxins that that are harmful to the human body. With this, it is used is condiment and flavor in foods and diets. Due to poor management, P. macrophylla is highly threatened as trees are indiscriminately felled without adequate replacement. It is recommended that adequate attention should be given to its conservation due to the prominent position it occupies in the cropping system of the region

Key words: *Pentaclethra macrophylla,* African oil bean, food security, economic empowerment, soil conservation

INTRODUCTION

Pentaclethra macrophylla, also known as African oil bean, is an herbaceous tropical tree crops popularly gown or cultivated in South-eastern and South-southern Nigeria. It belongs to the family *Leguminoseae* and subfamily *Mimosoideae*. It is found commonly growing in the different rainforest zones of Nigeria. Its cultivation is usually under semi wild or protected condition as homestead garden crops (Okigbo, 1975). *Pentaclethra macrophylla* seedlings are often not raised under nursery conditions but are transplanted from their point of germination, which usually occurs not far from where the mother plants are located. According to Okigbo (1975), *P. macrophylla* are found growing as volunteer's seedlings which are either nurtured to maturity at the point of germination or transplanted into another field. Due to its explosive dispersal mechanism, the seedlings are found growing in semi wild conditions. It is widely consumed as snack condiments (Mbata and Orji, 2008) and a delicacy especially in South-eastern and South-southern Nigeria (Odoemelam, 2005). Other uses are for medicine, soil improvement, environmental conservation and climate change mitigation. Occasionally, the trees are found thriving in the South western part of the country as forest trees. Due to the fact that they are not widely consumed in the part of the country, they are not given the desired attention. Consequently, *P. macrophylla* has lower tree density in the south west region compared to the south east and south southern part of Nigeria. In the east, it may be found cultivated under homestead conditions. During processing, *f*ermentation is needed to eradicate any toxins. Processing involves boiling, slicing and soaking of the seeds which reduces tannins and anti-nutritional compounds with an increase in iron, calcium, potassium, thiamine and riboflavin levels (Enujiugha and Akanbi, 2005) fats, carbohydrate (Oboh and Ekperigin, 2004).

Benefits of the African Oil Bean

The seeds, leaves, stems, barks, trunks and roots of the African oil bean tree are very useful for their nutritional, medicinal and economic values (Odunfa and Oyeyiola,1985). *P. macrophylla* contains high quantity of vitamins and minerals. The nutritional composition of *P. macrophylla* makes it a viable food type for combating food insecurity (Table 1).

MATERIALS AND METHODS

The study was conducted at National Horticultural Research Institute, Mbato Out-station field orchard, Okigwe in Imo State southeast geopolitical zone, Nigeria. Structured questionnaire was distributed to residents in Okigwe, Imo State to determine sources of seeds used for processing into consumable *P. macrophylla* salads and measures adopted for conservation within the cropping systems of the community. Data obtained were analyzed using descriptive statistics.

Table 1. Nutritional values of *Pentaclethra macrophylla*

Component	Values (%)
Crude protein	9.31
Crude fibre	21.66
Moisture	39.05
Carbohydrate	38.95
Ash	3.27
Oil content	47.90

Source: Ikhoria *et al.,* (2008)

RESULTS AND DISCUSSION

The sources of seeds for processing is presented in Table 2. Sources of collection of oil bean seed were NIHORT station (26.5%), Producers (8.5%), Farms (10%), purchase from market (4.5%), picking from people's farmland (28.5%), gathering from friend (2.5%) and gathering from forest (19.5%). Oil bean seeds are common in primary and secondary forest where they germinate freely and grow as semi wild plants. Most people interviewed got their seeds from NIHORT farms in Okigwe. However, the lowest percentage was recorded in those who obtained it from other people's farmlands. People in search of firewood and bush meat; easily pick *P. macrophylla* seeds which are dispersed on the field.

Table 3 shows methods used in conserving *P. macrophylla*. Thirty-five (35) percent of people did nothing to conserve oil bean, 42.5% planted more oil bean, 9% maintained and protected oil bean crops found around them, 22.5% disallowed felling of trees, 13.5% encouraged people to plant more to maintain the crops while 12.5% reestablished lost stands.

Table 3. Methods used in conserving oil bean

Methods	Frequency	Percentage(%)
Planting more oil bean	85	42.5
Maintaining/protecting oil bean crop found around.	18	9
Disallowing cutting down of trees	45	22.5
Encourage people to plant/maintain the crop	27	13.5
Replace old plants with new ones	25	12.5

Indiscriminate felling of trees and poor replacement plans can lead to genetic erosion and loss of this crop in the near future. Some efforts put in place by farmers towards conservation of the African oil bean tree include: restriction of indiscriminate harvest of oil bean tree by trespassers, prohibition of forest fires, and seizure of products from offenders and punishment of forest offenders through payment of fine among others. Felling of trees is practiced, but highly discouraged, as the tree is considered as an economic tree. This accounts for the lower frequency and percentage in use of restraints in cutting down of trees as a strategy for conserving *P. macrophylla* compared to planting of more trees. *P. macrophylla* is an underutilized tree with poor conservation status. Poor regeneration and low cultivation of *P. macrophylla* could make the crop go into extinction. Some stands of *P. macrophylla* are used as firewood leading to deforestation. Indiscriminate felling of trees contributes to tree loss and increase in adverse effect of climate change. Conservation efforts should include sensitization of people on the need to preserve forest trees for economic gains, ecological and genetic conservation. Policies should be put in place while trespassers should be charged for breaking the law.

CONCLUSION

P. macrophylla plays an important role in the food system of the south eastern and south southern Nigeria. It is necessary to conserve and preserve it for utilization in the food system of the people of the region

ABSTRACT

Landscape development has great benefits and impacts on the economic development and aesthetic appeal of most cities all over the world. This study was done to assess the effect of the various landscape practices adopted in selected LGAs of Lagos and Ibadan on the aesthetic perspectives of both cities. The study was carried out using a well-structured questionnaire to harvest relevant information about landscape practices in both cities. The questionnaire was divided into four sections which covered the socio-economic characteristics of respondents, assessment of landscape design, Maintenance practices, and Cultural/traditional beliefs about landscaping. A total of 114 responses altogether were collated and analyzed using spreadsheet analysis software (MS Excel) and Statistical Package for Social Science (SPSS), and data were presented in frequencies, percentages, and charts. Results obtained in Lagos showed that more Males (71.9%) than females (28.1%) are either involved in the act of landscaping or patronize landscape business. This was also true for Ibadan where 56.1% of Male was recorded, in contrast to 43.9% females. It was also recorded that the predominant purpose of landscaping in both cities is Beautification as it accounts for 87.7% of landscape purposes in Lagos, and 78.9% in Ibadan. Watering is the most practiced Maintenance routine in Lagos, with 87.7% of the respondents practicing it, in contrast to the 61.4% in Ibadan. 26.32% of respondents believe that Cultural/Traditional belief highly influences landscape business in Lagos, while 21.1% agree to the same assertion in Ibadan. Based on this study, it is concluded that the approach to uses of equipment and facilities differ at both locations, which is a reflection of the level of cultural belief, educational level, and probably the size of land and properties.

Key words: Assessment, Landscape Practices, Aesthetic Perspectives, Lagos, Ibadan, Metropolitan Cities

INTRODUCTION

Landscape is the visual properties or characteristics of the outdoor environment, which include natural and manmade elements, physical and biological resources (Amir and Gidalizon, 1990). Landscape practices serve as a form of trade in Nigeria, and an income generation source, apart from its primary function of beautifying the environment. Landscape practice is a service industry, which provides people with fabricated environments where man can live, work, and play, or just passes time (Asiedu et al., 2010). Metropolitan cities are cities with densely populated people in urban areas, having one or more towns connected together. Lagos is the largest Metropolitan city in Africa. It is located in the western part of Nigeria at the bank of the Atlantic Ocean. The wetland and urban region has an estimated population of 24.6 million, based on the UN-Habitat and international development agencies' estimates in 2015. In Nigeria, in particular important production and commercial centres are located in the cosmopolitan city of Lagos in South West Nigeria, alongside other cities in the humid rain forest which include Calabar in South-East and Port-Harcourt in South-South, while other centres characterized by the drier savannah vegetation include Abuja (the Federal Capital City) and Jos Plateau both located in the Middle Belt zone. (Olubode et al., 2015).

Lagos is of diverse ethnicity, due to the high rate of local and global migration, although, the dominant ethnic group is the Yoruba. It is a major financial Centre for all African countries, and the economic hub of Lagos State. It is referred to as a tourist haven, and it accounts for 180km out of Nigeria's over 700 km Atlantic sandy beaches, twenty of which are between Badagry in the west and Lekki in the east (Lagos state Government, 2006). Some of these beaches include: Bar beach, Lekki Beach, Kuramo Waters, Tarkwa Bay, Ogogoro Island, Eko Tourist Beach Resort, amongst others (Lagos State Government, 2019). The state also houses other numerous monuments and tourist attraction sites like the first Storey Building in Nigeria, Ologe Forest Reserve, Relics of Slave Trade, Egbin thermal station (largest power facility in Africa), Ijede water springs, Muritala Mohammed botanical garden, amongst others.

Likewise, Ibadan is the capital and the most populous city of Oyo, a south-west state in Nigeria. The suburban region is 128km inland northeast of Lagos (Oyo state Government, 2020) and it's the largest city in Nigeria by Geographical mass, but third largest behind Lagos and Kano in population. The city is estimated to have over 3.5 million inhabitants (Oyo State Government, 2020) and it's predominantly dominated by Yoruba. It is the prominent transit region between the coastal region and hinterland areas in the country, which makes it economically important. Ibadan houses various research institutes, monuments, recreational sites, and tourist attractions. Some of which includes; National Horticultural Research Institute, IITA forest reserve, Bower memorial tower, Agodi gardens, University of Ibadan Zoological and botanical garden, Cocoa research Institute of Nigeria, amongst others.

Landscape practices and business engagement have great potentials to uplift city status to either that of developed, under-developed or developing, with the accruing benefits including the value added to style of living, improved health status by way of alleviation of stress and development of a buoyant economy through financial in flow from provision of job opportunities and payment to garden owners for relaxation services rendered (Owolabi et al., 2020). Landscaping is widely known for enhancing the aesthetics perspective of an outdoor environment, as it can increase the value of a building during resale and present a relaxing view from the greenery of the environment. Plants are the most cost-effective and fastest agent of change that can eliminate the negative perception of an area, while enhancing the economic and social conditions, and improving psychosocial health (Relf, 1992). Landscape sights can function as healing landscapes, horticultural therapy, school gardening, community gardening and provides solutions on psycho-social issues (Relf and Lohr, 2003). Proper landscaping provides environmental benefits like air purification, reduction in noise pollution, reduction in cost of home heating and cooling, improving micro-climate, and also eliminating flooding, soil erosion, and oil spillage.

There is increasing evidence that exposure to plants and green space, and particularly to gardening, is beneficial to mental and physical health, and so could reduce the pressure on NHS services. It is not only the appearance of plants that is beneficial: their leaves remove toxins, dust and microorganisms from the air and they also produce the so-called negative ions from their leaves. (Perez *et al.,* 2013). Live indoor plants may increase workers' productivity and reduces stress. Landscaping contributes to the economic development of different states, countries, and metropolitan cites through protection of public and private structures against environmental hazards, revenue generation for the government, wealth creation and employment opportunities for individuals, attraction of tourists and investors, and lots more.

Public concern for the visual landscape has led to the widespread use of codified, replicable processes for assessing, documenting and predicting a landscape's scenic beauty (Bishop and Hulse, 1994). According to Ayuba (2019), there is insufficient data on landscape practices in terms of landscape design or the process of such designs in Nigeria; however, there is adequate data on the historical development of cities and their planning process. However, landscape practice is of great benefits and positive effects on the development and aesthetic appeal of Lagos and Ibadan. Thus, there's a need to assess the landscape practices in these metropolitan cities, to determine their strength, shortcomings, and impact on the city's aesthetic perspective and economy, while also proposing ways to further improve such practices in comparison to standard procedures. This will provide effective solutions to further improve the landscape practices in Lagos and Ibadan. The objectives of this study therefore are to evaluate the present landscape practices in Lagos and Ibadan; analyze the effects of landscape practice(s) on the aesthetic perspective of Lagos and Ibadan; evaluate the effect of landscaping contribution to cities development and growth; and determine the growth level and acceptance of landscape practice in Lagos and Ibadan.

MATERIALS AND METHODS

Survey location

This survey was carried out in Lagos metropolis and Ibadan Municipal city. Lagos is the most populous city in Nigeria, located in the south-west region and lies between Latitude: 6°27'14" N and longitude 3°23'40" E. The Mangrove rain forest region has an 11m elevation above sea level. It is the economic and commercial capital of Nigeria and the former political capital of the West-African country. Lagos has 20 Local Government Areas and 37 Local Council Development Areas. Landscape sites visited in Lagos include Ikeja, Oshodi-Isolo, Eti-Osa, Agege, Lagos-Island, and Amouwo Odofin Local Government Areas. Ibadan is the capital of Oyo state and the largest city in Nigeria by geographical mass. It is also located in south-west Nigeria and lies between latitude 7°22'39" N, and longitude 3°54'21" E. The humid rain forest region is 181m above sea level and comprises of 11 local governments area in its Metropolitan area. Landscape sites visited include Ido L.G.A, Ibadan South L.G.A, Oluyole L.G.A, and Akinyele L.G.A.

Methods

An estimated total of 20 landscape professionals was visited across Lagos and Ibadan and their opinion was sampled with aid of a structured questionnaire, and their responses were used for this analysis. A total of 140 copies of questionnaires were distributed in each of the combined ten (10) Local Government Areas visited in Lagos and Ibadan. A total 114 of questionnaires were retrieved in both cities, with both cities having 57 respondents each. Views of the various landscape sites and designs in both cities were captured with the aid of digital camera, for physical comparative analysis. The questionnaire had four (IV) different sections; **Section A** was used to determine the socio-economic characteristics and get personal information of respondents which includes gender, age, marital status, and educational status. **Section B** assessed the landscape practice in every site visited. It contained questions about the purpose of landscaping, property types, property size, materials and equipment being used, style of design, and average cost of design. **Section C** was used to get information about the maintenance practices being employed on established landscapes, in visited sites. It contained questions about frequency of maintenance, routine management practices, equipment used, cost of maintenance, and method of watering employed. **Section D** assessed the cultural/traditional beliefs of the respondents. It contained questions about the influence of their cultural/traditional belief on level of patronage, how they rate the city in terms of patronage, their experience about overflow of patronage, amongst others.

Data Analysis

Data collected using the demographics, aesthetics, and maintenance routine was analyzed using descriptive statistical tools and it was represented in percentages, bar charts, and tables. The questionnaire was collected, collated, and analyzed using spreadsheet Analysis software (M.s Excel) and Statistical Package for Social Science (SPSS).

RESULTS AND DISCUSSION

Demographic and Socio-economic characteristics of the respondent

The respondents that numbered 41 (71.9%) in numbers were male (Table 1), while 16 (28.1%) were females in Lagos, and 32 (56.1%) were male while 25 (43.9%) were females in Ibadan. This made up 57 respondents in each location and a total of 114 respondents in both locations combined. This table therefore shows that the males constitute higher percentage of the respondents in the study area. Age distribution of the respondents shows that in Lagos, 2 (3.5%) of the respondents were of the age 25yrs and below, 19 (33.3%) were of the age 26 – 40yrs, 24 (42.1%) were of age 41 – 55yrs and 12(22.1%) were 56 years and above. While in Ibadan, 9 (15.8%) were 25yrs and below, 19 (33.3%) were of the age 26 – 40yrs, 19 (33.3%) were of the age 41 – 55yrs and 10 (17.5%) were of the age 56 and above. This distribution indicates that the respondents who were of the age 41 – 55yrs constitute the highest percentage of the respondents in Lagos while those who are of the age 26 – 40yrs and 41-55 constitute the highest percentage of respondents in Ibadan. According to Owolabi et al., (2020), the gender sensitive and unmarried age brackets involved in the business indicated that more male were involved in the profession which could be due to the energy and time demanding nature of the most operations carried out in landscape work.

The respondents that numbered 49 (86%) were married and 8 (14%) were single in Lagos, while 40 (70.2%) were married and 17 (29.8%) were single in Ibadan. This result indicates that most of the respondents in both cities were married. Among the respondents about 29.8% and 42.1% worked for one company or the other which employed the use of landscape design while 33.3% and 38.6 were self-employed in Lagos and Ibadan, respectively. The respondents that numbered 24.6% in Lagos made daily income, while 7.0% did the same in Ibadan. Both cities had equal number of respondents of 12.3% on weekly wage. This result shows that Lagos had more self-employed landscape horticulturists than Ibadan, and more employers that employed the use of landscape designs.

Considering the educational level in Table 1, most of the respondents in Lagos and Ibadan (80.7% and 77.2% respectively) had tertiary education, 8.8% and 12.3% had secondary education, 1.8% had primary education in Lagos in contrast to none in Ibadan, and 3.5% had adult education in Ibadan in contrast to none in Lagos, 8.8% and 7.0% had Vocational education in Lagos and Ibadan respectively. This result shows that both cities had more learned respondents that are qualified enough to implement landscape design based on their level of experience. According to Asiedu (2010), some aspects of the practices does not require formal University education; however, others do. As observed in this study, the majority of people involved in landscape practices and business had formal education which indicated that landscape practice was a major employment opportunity for job seekers and could be a major economic force in the future. Furthermore, Fagbayide and Jonusa (2006) submitted that formal education enhanced appreciation and subsequently management of landscape work and that landscape practice is an elitist profession.

The respondents that numbered 43.9% in Lagos earned >500,000 as opposed 15.8% in Ibadan showed that there were more respondents in that category in Lagos than Ibadan. Nonetheless, Ibadan had more respondents earning <100,000 than Lagos (47.4% and 38.6% respectively), about 17.5% of the respondents in Lagos earned 100,000-500,000, while 36.8% earned within that range in Ibadan. This result shows that more of Lagos respondents were high income earners as opposed Ibadan that more dominated by middle- and low-income earners indicating the level of patronage and financial capacity of clients.

Assessment of landscape in Study Areas

The respondents that numbered 28.1% out of the study areas in Lagos were schools (Table 2), while school accounted for 24.6% in Ibadan. 26.3% accounted for hotel in Ibadan, in contrast to Lagos 10.5%. The table also showed that Hospitals were 10.5% in Lagos, and 8.8% in Ibadan. 50.9% of the remaining responses in Lagos accounted for other asset types, as against Ibadan's 40.4%. This shows that more schools were visited in Lagos, while more hotels were visited in Ibadan. The table also revealed that the most prominent cost of assets or input in Lagos and Ibadan was >₦500,000 which is 42.1% and 36.8% of total response in Lagos and Ibadan respectively, Ibadan also dominated the <₦ 100,000 assets costs, with 24.6% of the response, in contrast to 12.3% in Lagos. Lagos had 22.8% of the total assets within the range of ₦ 100,000 - ₦ 200,000, while Ibadan had 15.8% within the same range. 15.8% of total assets visited in Ibadan were within the range of 251,000-500,000, while Lagos had 14.1% within the same range. The distribution of landscape ownership shows that 66.7% of the respondents in Lagos owned the landscape property, while 68.4% accounts for the ownership in Ibadan. This result indicates that most of the respondents in Lagos and Ibadan owned the landscape while others were employed to manage for owners of the site. The respondents that numbered 42.1% and 45.6% of the landscape sites visited in Lagos and Ibadan, respectively were small plots. About 1.8% and 3.5% accounted for >10ha property size in Lagos and Ibadan, respectively, 31.6% and 35.1% were recorded for <1ha, while 24.6% and 15.8% accounts for 1-10ha. This result shows that Ibadan had more small plots of <1ha plot than Lagos, while Lagos property sizes were mostly 1-10ha. 40.4%, According to Owolabi et al., (2020), the more frequent occurrence of large hectarage sized properties observed in Lagos, Abuja and Ibadan in that order but of different ownerships in form of schools, social parks, gardens, and conference/recreation centres respectively showed the high space requirement of these businesses and the types of focuses of property owners in these cities.

Furthermore, the respondents that numbered 45.6%, 8.8%, and 5.3% accounted for the areas of landscape design done by Self, Landscape horticulturist, landscape architect, and Client's initiative respectively in Lagos, while 22.8%, 45.6%, 28.1%, and 3.5% accounted for the same in Ibadan. This result shows that most of the Landscape designs in Lagos and Ibadan were done by landscape horticulturists. The result in Table 2 indicated that 7% and 8% of the visited study area in Lagos and Ibadan, respectively were below one year of existence, 38.6% in Lagos and 52.6% in Ibadan had been in existence between 2-5 years, while 54.4% and 38.6% in Lagos and Ibadan, respectively were above 5 years of existence. Also, the table also revealed that the only respondents in Ibadan agreed that the landscape added value to the environment, while 55 (96.5%) of respondents in Lagos agreed that it added value to the environment. This agrees with the statement of Owolabi et al., (2020) that there is a general recognition of landscape business as a useful tool for enhancing property value. Lastly, the result in the table showed that the Landscape design influenced majority of the respondents in Lagos and Ibadan to use the public utilities. 87.7% and 91.2% in Lagos and Ibadan, respectively, agreed to this, while the landscape design didn't influence 12.3% of the respondent in Lagos and 8.8% in Ibadan to use public utilities

Assessment of Purpose of Landscape establishment in the Study Area

The respondents that numbered 89.5% and 78.9% in Lagos and Ibadan, respectively implemented landscape design for the purpose of beautification (Figure 1). About 8.8% of the respondents in Lagos were for advertisement, as opposed to 5.3% in Ibadan. Lagos had no response for business entrepreneurship and psychological therapy, while 3.5% of the respondents chose both categories for their purpose of Landscaping in Ibadan. This shows that majority of landscapes in the site surveyed were established for the purpose of beautification. Although Owolabi et al., (2020) identified different categories of business entrepreneurship which was not fully specified in this study and could have accounted for the response.

Soft Landscape Components in the respondent site

The response from the conducted survey showed that respondents in Ibadan used more of Lawns in their Landscape (Figure 2), than Lagos with both cities recording 17% and 14%, respectively. This probably was because of availability of abundant space in Ibadan compared to overpopulated Lagos with limited space. Also, more trees (15%) were also used by the respondents in Lagos than Ibadan (14%). This probably could be because of need to protect building from storms and need to ameliorate the effect of heat in the environment. The respondents that numbered 12%, 13%, and 11% in Lagos had hedges, shrubs, and palms, respectively, in their landscape, while 10%, 16%, and 6% had the same in Ibadan. This describes the choice of plant as ornamental palms are more prevalent in Ibadan. The respondents that numbered 1%, 3%,8%, and 4% in Lagos had established turf, green walls, bedding plants, and wild flower meadow, respectively, in contrast to the 2%, 5%, 3%, and 5% recorded in Ibadan. This corroborated earlier observation above of availability of space to accommodate the greens. About 10% of the respondent in both Lagos and Ibadan used local soft landscape components, while 3% in Lagos and 6% in Ibadan used exotic plants, respectively, while 6% in Lagos, and 14% in Ibadan represented the percentage of respondents who used mixture of both soft landscape components.

Hard Landscape Components in the respondent site

The respondents that numbered 18% and 15% of the respondent in Lagos and Ibadan, respectively used fences in their landscape, while 15% and 20% of the respondent in Lagos and Ibadan, respectively used walkway (Figure 3). This indicated that fences were the most used hardscape in Lagos while walkways were the most used in Ibadan. The respondents that numbered 17% in Lagos and 18% in Ibadan added car parks in their landscape, 4%,5%,5% and 6% of the respondent in Lagos added water fountain, pool, artifact and krebs in their landscape in contrast to 8%, 6%, 5%, 4% of the respondent in Ibadan. This response is as a matter of space availability rather than financial. Also, the trend of result in the table shows that no pergola was used in the landscape sites visited in both cities, 4%, 7%and 6% of the respondent in Lagos added irrigation system, paving, and gazebo while 6%, 7% and 1% accounts for the same components in Ibadan. Exotic, local and mixed hardscape were used by 2%, 8% and 8%, respectively by the respondents in Lagos in contrast to 1%, 3%, and 3% of the respondent in Ibadan. This describes the level of affluence, taste and financial capacity in Lagos compared to Ibadan in the use of more exotic hardscapes which probably were imported costly items for beauty.

Assessment of cost of designing and establishing the landscape in the study area

The respondents that numbered 1.8% and 3.5% in Lagos and Ibadan, respectively spent below 100,000 on the cost of establishing the landscape (Table 3), 15.8% and 17.5% in Lagos and Ibadan respectively spent between 1million naira – 5 million naira on cost of establishment while 22.8% in Lagos and 31.6% in Ibadan spent 500,000 – 1 million naira. Also, 35.1% of respondent in Lagos and 56.1% of that of Ibadan spent 100,000 – 500,000 naira on cost of establishment. This result shows that, Ibadan spends more on cost of establishment than Lagos across all price range. The respondents that numbered 43.9% in Lagos and 50.9% in Ibadan spent between 100,000- 500,000 naira to design their landscapes, while 21.1% and 22.8% in Lagos and Ibadan respectively spent less than 100,000 naira on design, 10,5% in Lagos and 12.3% in Ibadan spent greater than 500,000 on cost of design. This result shows that, the predominant cost of design in Lagos and Ibadan is 100,000 – 500,000 naira. Moreover, the higher expenditures in Ibadan compared to Lagos might indicate that Ibadan resident had more flare for beautiful environment than those in Lagos.

Maintenance practices adopted by the respondent in the study area

The analysis of the assessment of the management practices adopted by the respondent in both cities as shown in figure 4 indicates that higher percentage (22%) of the respondent in Lagos practice watering while (17%) in Ibadan do the same, weeding was carried out by 19% and 20% of the respondent in Lagos and Ibadan respectively. The table also revealed that 19% of the respondent in both Cities practiced trimming, while 11% and 12% of the respondent in Lagos and Ibadan, respectively practiced mowing. Operations like pruning, fertilizer application and pesticide application were practiced by 8%, 12% and 9% of the respondent in Lagos, respectively in contrast to the 9%, 8% and 15% in Ibadan. This result shows that watering, weeding, trimming and fertilizer application were the most common management practices in Lagos while watering, weeding and pesticide application were more commonly used in Ibadan.

Assessment on duration of maintenance in the study area

The respondents that numbered 19 (33.3%) in Lagos carried out daily maintenance practices as opposed 8(14%) of the respondent in Ibadan (Table 4), weekly and monthly maintenance practices were carried out by 16(28.1%) and 22(38.6%) of the respondent in Lagos in contrast to 19(33.3%) and 30(52.6%) of the respondent in Ibadan. The table also shows that 3.5%, 29.8% and 66.7% of the respondent in Lagos mow their lawn daily, monthly and weekly

ISSN: 2814-0508

respectively while 5.3%, 33.3% and 61.4% of the respondent in Ibadan does the same, more of the respondent in Lagos and Ibadan (66.7%) and (54.4%) respectively trim their hedges weekly, 1.8% of the respondent in both cities carries out hedge trimming practices daily while 31.6% of the respondent in Lagos and 43.9% of the respondent in Ibadan trim their hedges monthly. The tree litter packing frequency, displayed in the table shows that 78.8% of the respondent in Lagos pack their tree litter daily while 56.2% of the respondent in Ibadan does the same, no respondent in Lagos packed their tree litters monthly but 14% of the respondent in Ibadan does, 21.1% of those in Lagos and 33.3% of those in Ibadan pack their tree litters weekly. Lastly Table 4 shows that majority of the respondent 66.7% and 64.9% in Lagos and Ibadan respectively apply manure to their landscape site monthly while 31.6% of the respondent in Lagos and 35.2% of the respondent in Ibadan carry out manure application weekly. Only one (1.8%) respondent in Lagos chose daily application in contrast to none in Ibadan.

Assessment of equipment used in maintaining the landscape sites visited

The respondents that numbered 32% and 33%, respectively in Lagos and Ibadan used hedge trimmer, 25% of the respondent in Lagos and 23% of those in Ibadan used push mower (Figure 5), 15% and 10% of the respondent in Lagos and Ibadan, respectively used brush cutter, while the use of cutlass was employed by 27% of the respondents in Lagos compared to 24% of the respondents in Ibadan. The figure also shows that 8 of the respondents in Ibadan (10%) had tractor mower in contrast to 1 (1%) in Lagos. This obviously is in support of the wider space for lawn and ground covers in Ibadan compared to Lagos.

Assessment of irrigation method adopted by the respondent in both cities

The respondents that numbered 38.6% and 54.4% in Lagos and Ibadan, respectively used sprinkler irrigation system (Figure 6), while 47.4% and 24.6% of the respondents in Lagos and Ibadan, respectively used rubber hose. 10.5% and 3.5% of the respondents in Lagos practiced drip irrigation and furrow irrigation method in contrast to the 19.0% and 7.0% in Ibadan. This result shows that sprinkler irrigation was more adopted in Ibadan as opposed the rubber hose being predominantly used in Lagos. The adoption of irrigation methods to support and supplement rain fed production agrees with findings of Olubode et al., (2015) that here exists a proportionate supportive threshold required for soil moisture indicating that rain-fed rose as well as related ornamental plants' cultivation would require supplemental irrigation for effective productivity

Assessment of cultural/traditional beliefs of respondent in the study area

The respondents that numbered 27% and 11% in Lagos and Ibadan, respectively believed that plants attract reptiles (Table 5), while 21% of respondent in Lagos and 22% of respondent in Ibadan agrees that some plants scare away reptiles, 25 (19%) of the respondent in Lagos believes maintaining plants cost more than landscape cement flooring while 20% of the respondent in Ibadan also agrees to that. 4% and 7% of the respondent in Lagos and Ibadan respectively were of the opinion that plants are cheaper to maintain compared to landscape cement flooring. The table also showed that 27% of the respondent in Lagos and 40% of the respondent in Ibadan believed that plants cool and beautifies the environment, 2% of Lagos respondent were undecided in contrast to none in Ibadan. Most of the respondents in Lagos and Ibadan, 50.9% and 52.6%, respectively believed that cultural/traditional beliefs have moderate influence on landscape business patronage, 26.3% of the respondents in Lagos and 21.1% of Ibadan respondents were of the opinion that cultural/traditional beliefs have high influence on landscape business patronage. The table also showed that 12.3% and 19.3% of the respondents in Lagos and Ibadan respectively agrees that cultural/traditional beliefs have no influence on landscape business patronage, the remaining of the respondents which are 10.5% in Lagos and 7.0% in Ibadan were undecided.

The respondents that numbered 38.5% of the respondents in Ibadan described the items of natural heritage valued within the city as few but highly valued while 31.6%of the respondents in Lagos shared the same view about their city, 5.3% and 3.5%

of the respondent in both Lagos and Ibadan believed the items of natural heritage were few but rarely valued, 33.3% of the respondents in Lagos and 21.1% in Ibadan were of the opinion that they were many and highly valued while 29.8% and 24.6% in Lagos and Ibadan respectively believed they were many but rarely valued, 7(12.3%) of the respondent in Ibadan were undecided. The respondents that numbered 10.5% and 8.8% in Lagos and Ibadan respectively believed that landscape practices add value to the environment, 7.0% in Lagos and 19.3% in Ibadan believes landscape practices attracts more customers. 54.4% and 36.6% in Ibadan and Lagos respectively believes landscape has enhanced the aesthetic appeal of the cities, 5.3%, 19.3% and 19.3% of respondent in Lagos believes that landscape helps cool the environment, improves the economy and aids tourist attraction in the city respectively while 7.0%, 10.5%, and 0% believes the same in Ibadan, respectively.

Assessment on categories of patronage in both cities

The respondents that numbered (51%) and (58%) respectively in Lagos and Ibadan had more patronage for moderate cost design (Table 6), 23% of the respondent in Lagos adopted low-cost design in contrast to the 25% of the respondent in Ibadan. 19% and 14% of the respondent in Lagos and Ibadan respectively patronized high-cost design while 7% and 3% of the respondents in Lagos and Ibadan chose the executive type. The respondents that numbered 47.4% in Lagos rated the city high in terms of patronage compared to other neighboring cities, while 21.1% of the respondent in Ibadan did the same, 36.8% and 12.3% in Lagos and Ibadan respectively rated both cities patronage moderately while 5.3% of the respondents in Lagos and 1.8% in Ibadan rated it low. The table also shows 8.8% and 1.8% of the respondent in Lagos rated the patronage very high and very low respectively while 38.6% and 14% did the same in Ibadan. No respondent was undecided in Lagos as opposed 7(12.3%) in Ibadan. Most of the respondents in Lagos (64.9%) believes over flow of patronage from neighboring cities for landscape business is few while 36.8% believes the same in Ibadan, 29.8% of the respondent in Lagos believes the over flow is large while 47.4% believes the same. The table also shows that 5.3% and 15.3% of the respondent in Lagos and Ibadan respectively were undecided.

CONCLUSION

In Conclusion, although both cities had high influence of educated practitioners among the respondents, however availability of space, choice of plants, the level of affluence, taste and financial capacity were prominent issues that differentiate the practice of landscape business in both cities. Although cultural beliefs played prominent roles in peoples' choices and behaviors but there was no significant influence observed in the differences. The majority of landscapes in the site surveyed were established for the purpose of beautification, while the approach to uses of equipment and facilities differed at both locations, which is a reflection of the level of cultural belief, educational level, and probably the size of land and properties adopted, however only Ibadan respondents had business entrepreneurship and psychological therapy in their concerns.

ABSTRACT

The study proposed a prototype design for the establishment of Nigerian Botanical Garden with some selected ornamental plants species that can enhance provision of ecosystem services and sustainable heritage garden development. It was based on the concept of ecological landscape and computer- aided architectural design, which was used as determinants in the formulation of floor, site layout plans and animation production. The study revealed that: Botanical Garden prototype designed ranged from site layout plan, building (9825mm by 19870mm), elevation and perspective drawing using plant species Erythrina indica, Roystenea regia, Phoenix dactylifera and Eucepalartos barteri as less varieties and more repetition species and Acacia moniliforms, Mussaenda erythrophylla, Codiaeum variegatum, and Plumera rubra as more varieties and less repetition species. The study proposed that, plant species families of Apocynaceae, Arecaceae, Zamiaceae, and Euphorbiacea out of 8 families would be good candidates for ecosystem services such as: aesthetic, pollutant removal and air quality improvement, while the families of Fabaceae, Myrtaceae, Rubiaceae and Araucariaceae would be good candidate for shading, human health and well-being, climate change mitigation, biodiversity conservation and heritage garden sustainability.

Key words: Botanical garden design, plant species, sustainability and ecosystem services

INTRODUCTION

The word garden rooted in two Hebrew words "*gan*" and "*oden*" meaning to shelter and inclination or utopia when the two words are combined, it means the enclosure of land for inclination and amusement. A botanical garden (BG) is a well-ordered and staffed establishment for the conservation of plants under scientific administration for purposes of education and research, in association with libraries, herbaria, laboratories, and museums as are essential to its particular enterprise. Each botanical garden generally cultivates its own special fields of interests reliant on its personnel, location, extent, available funds, and the terms of its charter. It may include greenhouse, a herbarium, an arboretum and other divisions of grounds. It maintains a scientific as well as a plant-growing staff, and publication is one of its major means of communication (Bailey and Bailey, 1978).

Botanical Garden design is a regenerative design which is the bio-mimicry of the biological system describing processes that restore, renew or revitalize their own sources of energy and materials, creating sustainable systems that incorporate the needs of society with the reliability of nature. It is also an outline to biological systems that can heal cities and its inhabitants through bioremediation, living architecture, and innovative water management with emphasis on an overview of urban toxicology, environmental issues, environmental justice, phytoremediation, bio-filtering, use of plant species and tree, grass, plant selection for pollution reduction. (McDonough and Micheal, 2001).

With regard to folklore the popular religions both Christianity and Islam define garden as a form of paradise. Muslim describes it as the commencement and the end of life on earth. The promised garden of Muhammed was said to be filled with groves of trees and fountains where pleasure which lasted for a brief moment on earth will be prolonged thousand years. The Christian believers considered that man was created and put in the Garden of Eden, a form of worldly paradise. With the colonization of Nigeria by the British has come the infusion of foreign and exotic garden style into the traditional styles. However, there is truly a Nigerian garden style or styles that could be attributed to the several cultural groups notably the Yoruba, Hausa, Igbo, Kanuri, just to mention a few (Falade and Oduwaye, 1998), hence the necessity for establishment of Nigerian Botanical Garden. Against this background, the study set out to achieve the objective of design a prototype national botanical garden structure with tree species either exotic or indigenous that has the potential to enhance the provision of ecosystem services, biodiversity conservation and sustainable heritage garden development.

MATERIALS AND METHODS

Collection of Plant Specimens

The study was carried out on 10 selected ornamental plant species (Table 1). Fresh leaves were collected at ornamental nursery site in Ilorin, Kwara State. The voucher specimens of all the collected plants were deposited at the University of Ilorin Herbarium, Plant Biology Department. Identification and nativity was done using local floras (Keay et al., 1990).

Table 1. Proposed Selected Ornamental Plants Species for the Planting Plan Design

	Plant Species	Common Name	Family
1	*Roystenea regia* (Kunth) O.F.Cook	Royal palm	Arecaceae
2	*Phoenix dactylifera* L.	Date palm	Arecaceae
3	*Eucephalartos barteri* Carruth.ex Miq	Cycad	Zamiaceae
4	*Codiaeum variegatum* (L.) Blume	Croton	Euphorbiacea
5	*Acacia moniliforms* Griseb.	Acacia	Fabaceae
6	*Eucalyptus citriodora* Labii	Eucalypt	Myrtaceae
7	*Erythrina variegata* L.	Coral tree	Fabaceae
8	*Araucaria heterophylla* (Salisb) Franco	Araucaria	Araucariaceae
9	*Plumera rubra* L.	Frangipani	Apocynaceae
10	*Mussaenda erythrophylla* Schum. & Thorn	Queen of Philipines	Rubiaceae

Design Process with Plant Species

Application of some basic design process (site analysis, aesthetic, spacing, selection, climatic and soil characteristics) and principles of design was used in the of prototype botanical garden site layout plan. These principles consist of various uses of line, form, texture, colour, repetition, variety, balance and emphasis. All of these terms apply to any aesthetic composition or work of art. Scale: more variety and less repetition can be used in a small-scale design such as a residential garden and in contrast to a large-scale design such as an urban park (Carpenter et al., 1990).

Computer Aided Architectural Design

This was based on the concept of ecological landscape design, which is the recognizing and mapping out natural processes in the landscape and this was used as determinants in the formulation of floor plan, elevation plan, animation production and perspective of the prototype botanical garden (McHarg, 1995; Chen et al., 2008).

Data Analysis

Introduction of shape grammers to computer software application packages - Auto-Cad 2018 was used to developing a system for interactive manipulation of architectural floor, site layout, elevation and perspective plans.

RESULTS AND DISCUSSION

Design Process with Plants Species

The site layout plan (Fig.1) is a land planning for bigger scale advancement involving subdivision into several or many parcels, including analyses of soil and landscape, feasibility studies for economic, social, political, research, technical, conservation and ecological constraints. In practice, the layout design plans rely on a deep understanding of human comfort, needs, habits, and social relationship. Exterior trim, as well as distinctive windows and entrances were used in the perspective drawings (Fig.2). The significance of these results is that the planning and design which are based on idealized (prototype) and does not take into account the numerous site and client-specific factors that are measured by the architects. According to Falade and Oduwaye (1998), many people narrowly conceive architecture as the design of buildings; it has also become necessary to extend the same argument to the garden, therefore, the site layout plan design is la-di-da by the local climate and cultural heritage, the views from environmental concern help in customizing the building as shown in the perspective drawings.

Figure 1. Prototype Botanical Garden Site Layout Plans

Figure 2. Perspective of the Prototype Botanical Garden

Computer Aided Architectural Design

Through prototyping, the schematic plans were refined into a detailed floor plan, at this stage wall classifications were pinned down and doors, windows and open walls were precisely specified. The individual components of the present design are: the prototype botanical garden structure floor plan organization (Fig.3) and elevation plan (Fig.4). The floor plan was used to construct the elevation plan, while the remaining square footage of land was developed to green area, recreational arena with proper organization of ornamental plants (Table 1) to bring out the aesthetic values of the prototype national botanical garden design. This was in line with the findings of Carpenter et al. (1990) that to create an ordinary garden, knowledge of horticulture is enough, but to create a commercial garden as an art requires the use of the skillful art of designer, horticulturist and landscape architect.

CONCLUSION

The overall implication of this study is that most of the gardens visited during the course of this research work have useful plant species similar to the proposed one in the materials and methods and can be replicated in the proposed national botanical garden. This could serve the purpose of educational, research, conservational and commercial value, human health and wellbeing, climate change mitigation, national identity and sustainable cultural heritage garden development with minimum pollution level.

ABSTRACT

Home gardens can be described as a mixed cropping system that encompasses crop (vegetables, fruits, plantation crops, spices etc.) and livestock (goat, sheep, cow, poultry etc.) that can serve as source of food and income. The study was carried out in various locations across Nigeria particularly NIHORT- neighborhood in the states where the Institute is situated (headquarter in Ibadan-Oyo, Dadinkowa- Gombe, Bagauda- Kano, Mbato- Imo states). Structured questionnaire was administered to 412 home garden owners sampled across NIHORT-neighborhoods. Data collected was analyzed using descriptive statistics such as frequencies and percentages. Findings revealed that goat was the most common free-range animal observed in home gardens; 70.2% of the home gardeners do not allow free-range in their gardens while 57.7% believe that free-range animals affect home gardens. A little less than half of the respondents (47.6%) do not allow free-range animals in their home gardens due to the destruction they cause to the gardens. Season of the year was found to affect the activities of free-range animals in home gardens (67.2%). Home garden owners in the study area observed that the activities of free-range animals on their home gardens are not palatable as the animals are observed to feed on the crops in home gardens. It should be advocated that animals on free-range should be properly managed and controlled to minimize or reduce the damage in home gardens.

Key words: Home gardens, Free range animals, sources, types, seasonality

INTRODUCTION

The world population is increasing daily, if the population is to be fed adequately, the present food production level will have to be doubled and other strategies encouraged. One of such strategies that need some level of assessment is homestead farming (Ndaeyo, 2007). Home gardens can be described as a mixed cropping system that encompasses vegetables, fruits, plantation crops, spices, herbs, ornamental and medicinal plants as well as livestock that can serve as a supplementary source of food and income" (Galhena et al., 2013). They serve as a remedy for alleviating hunger and malnutrition as they contribute to food and nutrition security. Home gardening is an ancient practice worldwide. The main objective of home gardens is to grow and produce food items for family consumption as well as diversified to produce output with multiple uses such as indigenous medicine, alternative fuel source, manure, animal feed, among others (Gahlenna et al., 2013). Home gardens are a reputable source of diverse animal and food items that help in increasing dietary intake of household members while building their bioavailability and absorption of essential nutrients (Talukder et al., 2000). Livestock and poultry activities integrated into home gardens help reinforce food and nutritional security of households as they serve as a source of animal protein (de la Cerda et al., 2008).

Free range is a system of animal husbandry which usually offers the opportunity for the extensive locomotion and sunlight for the animals that is otherwise prevented by indoor housing systems. Animals that are reared in free-range systems include pigs, poultry, turkey, livestock, dairy, among others (Wikipedia, 2021). Free-range animals provide disposable cash income to poor households (Hailemichael et al., (2016). Free-range method of animal husbandry was originally concentrated in villages, while increasing urbanization has resulted in the growth of village type livestock in urban and peri-urban areas which is often called "backyard production" (Thieme et al., 2014) alongside with garden crops. Family poultry according to Thieme et al. (2014) was described as the full variety of all small-scale poultry production systems found in rural, peri-urban and urban areas of developing countries. Livestock in home garden helps provides quality nutrient of high biological (protein) value inform of food (egg, milk and meat), energy, fertilizer, diversify incomes and a renewable asset in over 80 percent of rural households (Thieme et al., 2014; Sonaiya and Swam, 2004). Moreover, the Federal Ministry of Agriculture and Rural Development (FMARD, 2017) report noted that in the year 2017, the number of livestock produced in Nigeria was 180 million poultry, 76 million goats, 43.4 million sheep, 18.4 million cattle, 7.5 million pigs, 1.4 million equids (horses, donkeys, etc.). It was also observed that most animals raised in Nigeria are on free-range production systems which comprise of smallholders and nomadic herders (FMARD, 2017). The integration of livestock activities into home gardening can expedite nutrient cycling in ecosystem and help retain moisture. (Powell and Williams,1993). Home garden, plant materials are used as fodder for the animals and animal manure is incorporated into the compost to fertilize plants, hence reducing the need for chemical fertilizer (Mitchell et al., 2004). Part of basic important component of livestock management practices are housing, and feeding, sanitations and medications with feeding taking up to 80% of livestock production cost. In Nigeria, traditionally, animals are kept in house fenced made of bamboo, roofing sheet, planks or wood in the home garden. These animals are also allowed to roam about fending for themselves with little or no supplementation from the owners. Arising from the foregoing, it is imperative to assess the activities of free-range animals in home gardens as it has been observed that these animals can serve as an integral part of home gardens.

MATERIALS AND METHODS

Structured questionnaires were developed and administered to home garden owners. Purposive sampling was used to select 412 home garden owners within 10 km radius of NIHORT-neighborhood across the geopolitical zones where the Institute is located: the headquarters Ibadan, Oyo State (South West) and substations like Dadinkowa Gombe State (North East), Bagauda Kano State (North West) and Mbato Imo State (South East). Data was collected using a structured questionnaire to assess the activities of free-range animals in home gardens across the selected locations. Of the 412 home garden owners sampled data used for analysis was obtained from 366 home gardeners. This data was analysed using descriptive statistics such as frequency and percentages.

RESULTS AND DISCUSSION

Types of Animals found on free-range

The table (1) reveals that goat is the most commonly found free-range animal (47.8%) in home gardens in the study areas. The finding is in agreement with Duku et al. (2010) that goats have the highest percentage of free range activity in Ghana. Most of the home garden owners (70.2%) opined that free-range animals should not be allowed in home gardens and 57.7% also believe that these animals affect home gardens. One-third of the respondents also noted that free-range animals are cheap to manage when they have access to home gardens. However, 47.6% opined that they do not allow free-range animals in their home gardens because the animals cause destruction to garden crops.

Other Activities of free-range animals in home gardens

More than half of the respondents stated that free-range animals are from their neighborhood (51.4%) while twenty-nine percent observed that the whole of their garden is affected by these animals. Moreover, season of the year affects the activities of free-range animals (67.2%) which 44.3% of the home garden owners attested that these activities is mostly felt in the dry season. (Table 2). This could be due to the fact that the free-range animals have to scavenge for food in the dry season due to scarcity of forage.

Source; Field survey, 2017

CONCLUSION

Findings revealed that goat was the most common free-range animal observed in home gardens. Also, majority of free range animals are from neighborhood of the garden, whose activities leads to destruction of the garden crops especially during the dry season. It should be advocated that garden owners should protect their garden crops from destruction by free range animals in their neighborhood. Also, a low cost fencing and housing facilities could be made by garden owners for their livestock in order to get the best of the garden products (crop & livestock) in the farming system.

ABSTRACT

With the purpose of studying data on spontaneous customary changes in wistar rats and effect of biogro (bio fertilizer) on organ enzymes (serum biochemistry), we administered food laced with dried okra treated with the biogro. This study was carried out at three different places which are the animal experimental house, water hyacinth, National Horticultural Research Institute (NIHORT) Ibadan, Oyo state, Nigeria, the Clinical pathology laboratory, University of Ibadan, Nigeria and the histopathology laboratory at the Department of Veterinary Pathology, Faculty of Veterinary Medicine, University of Ibadan, Nigeria. A total of 32 wistar rats were used for the experiment, with the rats divided into eight groups. Four rats occupy a unit/cell of the cage, making it eight treatments replicated four times. The experiment was laid out in complete randomized design (CRD) and data were analyzed with one-way analysis of variance (ANOVA). The biogro treatments (treated on okra plants) were administered daily as it was included in the feed given for five days (acute toxicity test). On the termination of the experiment, all the rats were observed not to have any behavioral changes as they all appear and were normally behaved, and sacrificed, blood samples were taken for analysis. At the end of the experiment it was observed that the treatment had no significant effect on both the blood parameter AST = Aspertate amino transferase, TB = Total bilirubin, EO = Eosine, ALP = Alkaline Phosphate, ALT = Alanine amino transferase, TP = Total protein, ALB= Albumin, GLB = Globulin.

Key words: Biogro, serum biochemistry, wistar rats, plant hormone

INTRODUCTION

Serum biochemical assessments are relevant tools in evaluating the physiological and pathological status of mammals and birds, as they provide information for the proper diagnosis of diseases, making a prognosis, evaluating the efficacy of instituted therapy, and toxicity of drugs and chemical substances (Stockham and Scott, 2008). Serum biochemical assessment helps to predict pathological processes in the vital internal organs of the body such as the liver, muscle, heart, pancreas and kidney (Stockham and Scott 2008). It also helps to establish the presence or absence of disease of an organ, and determine the nature and extent of a disease process (static, progressive or regressive) by serial performance of laboratory tests of the internal organs.

Several physiological factors have been known to affect the serum biochemistry parameters in apparently healthy rats. These factors are breed, sex, age, reproductive status; time of feeding, diurnal variations, nutritional state and management; and geographical/climatic factors such as temperature, humidity, altitude and day length (Weiss and Wardrop, 2010). Alterations in serum biochemistry values can be attributed to poor sample handling, stress during blood sample collection, blood sampling techniques, presence of an inhibitor such as anticoagulant and stress of capture (Stockham and Scott, 2008).

In available literature, there are reasonable amount of haematological and serum biochemistry values of rodents such as the birch mouse (Wolk 1985), juvenile laboratory rat (Ihedioha et al., 2004), African soft-furred rat (Kagira et al., 2005), wild grasscutter (Opara et al., 2006) and adult wild African giant rat (*C. gambianus*) (Oyewale et al., 1998a, 1998b; Olayemi and Adeshina, 2002; Cooper and Erlwanger, 2007), but only little information is available on the haematology and serum biochemistry values of the juvenile wild African giant rat (Nssien et al., 2002; Onwuka et al., 2003). Due to the variations in the haematological and serum biochemistry values, there is need for each clinic to establish its own reference range of values for relevant animal population. Also, due to the popularity of this rodent, efforts have been made to domesticate and keep them as pet, and attempts have also been made to use them as laboratory animals (Olayemi and Adeshina 2002).

Justification

Agrochemicals or even plant hormones such as fertilizing elements are essential to boost agricultural/horticultural production in Nigeria. The usual practice is to recommend "appropriate" doze due to observed increase in yield. However, there is the need to continue to monitor the residual effects of these agrochemicals or plant hormones so as to ensure they have no residual effect or at least, that the residuals are within safe limits recommended by regulatory authorities such as WHO and FAO. Hence, our recommendations will no longer be based on quantity (yield) only but also on food quality. The objectives of the study are: 1) To observe treated animal for behavioral changes and 2) To investigate the serum biochemistry of treated animal for possible effect.

MATERIALS AND METHODS

This study was carried out at the animal experimental house, water hyacinth National Horticultural Research Institute Ibadan Oyo state, Clinical pathology laboratory, University of Ibadan and Histopathology laboratory of the Department of Veterinary Pathology, Faculty of Veterinary Medicine, and University of Ibadan, Nigeria.

A total of 32 wistar rats were used. The rats were divided into eight groups (treatments) with four rats occupying a unit/cell of the cage, making it eight treatments replicated four times and the rats were acclimatized for one week before commencement of treatments. Feed and water were given to the animals during acclimatization ad-libitum. The biogro treatments were administered daily as it was included in the feed given for five days (acute toxicity test). On the termination of the experiment, all the rats were sacrificed and organs of interest were carefully removed through cervical dislocation for diagnosis. These include the liver and kidney for histopathological examination. The experiment was laid out in completely randomized design (CRD) and data were analyzed with one-way analysis of variance (ANOVA), group means were compared for significance at 95% confidence level (P 0.05) by Duncan's Multiple Range Test (DMRT) from SAS 2003.

Blood Sample Collection

Blood samples for the serum biochemical determinations were collected from the orbital sinus of the 32 wistar rats following the procedure of Stone (1954). These samples were collected between the hours of 8 and 11 in the morning on the same day. Blood samples (1 ml) for haematology were collected into sample bottles containing ethylene diamine tetra acetic acid (1 mg/ml of blood). For serum biochemical analysis, 3 ml of blood was put into plain glass tubes and sera harvested within 1 h after centrifuging the clotted blood with a clinical table centrifuge at 3000 rpm for 15 min. The haematological and serum biochemical analyses were carried out immediately upon blood collection

Biochemical Parameters

Serum samples were analyzed for the activities of aspartate aminotransferase (AST), alanine aminotransferase (ALT) and for the concentrations of total protein, albumin, cholesterol, total and direct bilirubin, alkaline phosphate and urea by the Roche Diagnostic Hitachi 902 Analyzer**.**

Haematological and serum biochemistry procedures Haematological and serum biochemistry determinations were carried out following standard procedures. PCV was determined by the micro-haematocrit method (Thrall and Weiser, 2002), Hbc was determined by the cyanomethaemoglobin method (Higgins et al. 2008). RBC count and total leukocyte count (TLC) were carried out by the haemocytometer method (Thrall and Weiser, 2002), differential leukocyte count was done by making a blood smear on a clean glass slide and staining it following the Leishman technique. The different cells of the leukocytic series were enumerated by the battlement counting method (Thrall and Weiser, 2002). The mean corpuscular values – mean corpuscular volume (MCV), mean corpuscular haemoglobin (MCH) and mean corpuscular

ISSN: 2814-0508

haemoglobin concentration (MCHC) – was calculated using the standard formulae (Coles, 1986). Serum biochemistry determinations were carried out using commercial test kits, Quimica Clinica Aplicada (QCA) test kits (QCA, Spain), Randox test kits (Randox, UK) for total proteins and albumin, and a digital colorimeter. Serum ALT and AST activities were determined by the Reitman–Frankel method (Reitman and Frankel, 1957). Serum ALP activity was determined by the phenolphthalein monophosphate method (Babson et al., 1966), while total serum proteins were determined by the direct Biuret method (Lubran, 1978). Serum albumin was determined by the Bromocresol green method (Doumas et al., 1971). Serum globulin was calculated as the difference between serum total proteins and serum albumin (Colville, 2002), while serum total bilirubin was determined by the Jendrassik–Grof method (Doumas et al., 1973). BUN was determined by the Berthelot–Searcy method (Fawcett and Scott, 1960), while serum creatinine was determined by the modified Jaffe method (Blass et al., 1974). Serum cholesterol was determined by the enzymatic colorimetric method (Allain et al., 1974).

Table 1. Effects of treatments on serum biochemical parameters of wistar rats

Treatment	ALT (U/L)	ALB(G/DL)	GLB (G/DL)	TP ($x10^6/mm^3$)	AST (U/L)	EOS ($x10^6/mm^3$)	ALP ($x10^6/mm^3$)
T1	7.63a	1.93b	4.33a	0.63a	34.33ab	2.00a	25.67c

Means within the same column followed by the same letter(s) are not significantly different at $P < 0.05$ using DMRT

AST = Aspertate amino transferase, TB = Total bilirubin, EO = Eosine, ALP = Alkaline Phosphate, ALT = Alanine amino transferase, TP = Total protein, ALB= Albumin, GLB = Globulin

RESULTS AND DISCUSSION

There was significant difference in Aspertate amino transferase (AST) of animals treated with biogro and biofart, while there was no significance difference from observation made among the other treatments (total protein, Eosine, Globulene and Alkaline Phosphate) and the control. However, the rats treated with T5 recorded highest means value while the lowest mean value was obtained from T2. There were no significant differences in ALT, total protein, globulin and eosin in all the treatments compared with the control but T8 was highest in mean value and lowest in the control with respect to ALT. In Total protein, control had highest mean value while T8 recorded lowest mean value, and in Eosin the highest mean value was observed in animals treated with T6 and lowest in T4 as seen in Table 1.

The results showed that there was significant difference in ALP between treatments, highest in mean value was observed control while T2 recorded lowest mean value. There was significant difference in the control and treatments for albumin where T8 had the highest mean value and treatment with T1 had the lowest mean value from Table 1.

All rats treated with biogro showed a marked increase in body weight gain and the rats showed no signs of poisoning and this is in agreement with the work of Mansour et al. (2007) that there were no signs of Toxicity noted in rats treated with plant growth hormones.

The trend in lymhpocytes revealed highest mean value in animals treated with T2 and lowest in T7 as shown in Table 1, the normality found in serum levels of protein for all the rats dosed at all dosages of treatment shows that the treatment is not toxic to the organs or health of the animals as reported in the findings of Das and Mukherjee (2000) that toxicants may cause stress-mediated mobilization of protein to cope with the detrimental condition so imposed. The protein mobilized is one of the strategies employed to meet the energy required to sustain increased physical activity, biotransformation and excretion of the toxicants.

Amino transferases (ALT & AST) are produced in the liver and are good markers of damage to liver cells but not necessarily the severity of the damage as reported by (Olav et al., 2007; Rej, 1989). The non-significant levels of EOS, TP, GLB and ALT in treated groups could be as a result of suppression of production by the liver which is in agreement with Obaineh and Mathew (2009) that they are normally present at low levels in the blood so if the liver cells are damaged, it would be expected that some of the enzymes leak into the blood and increase the levels.

Decrease levels of albumin may be due primarily to reduction in synthesis by the liver and secondarily to reduced protein intake which further confirms no hepatic damage and agree with the works of Luskova et al. (2002) and Jyotsna et al. (2003) as observed in WBC in the study.

In contrast to serum enzymes, albumin apart from being a useful indicator of the integrity of glomerular membrane is also an important indicator in determining the severity of disease as also stated by Lawrence and Amadeo (1989) and (Mukut et al. (2001). In the histopathological evaluation of the liver and kidney of rats treated with biofart and biogro showed no injury as there was no visible lesion observed neither was any severe damage in terms of necrosis observed in any of the organs of the treated animals and this is in agreement with the work of McCormack (2011). In the various treatments, the only observable change is an increased vascular congestion ranging from mild to moderate. The treatments do not have a structural change on the tubules and other anatomic structures in the kidney. The toxicity effects of treatments are not acute as the clinical symptoms did not manifest in test animals.

CONCLUSION AND RECORMENDATION

The report above has shown that the treatments had no significant effect on the behavior, serum biochemistry and on the health of the test animals hence, it is safe for use at the recommended dosage. It is hereby recommended based on this finding that the test product is safe for use at the recommended standard dosage.

Acknowledgement: We sincerely appreciate the efforts and encouragement received from Dr. A.O. Oke (former head of Vegetable Program, NIHORT, Ibadan, Nigeria) during the process of this research.

ABSTRACT

This study was carried out at three different places which are the animal experimental house, water hyacinth, National Horticultural Research Institute (NIHORT) Ibadan, Oyo state, Nigeria, the Clinical pathology laboratory, University of Ibadan, Nigeria and the histopathology laboratory at the Department of Veterinary Pathology, Faculty of Veterinary Medicine, University of Ibadan, Nigeria. A total of 32 wistar rats were used for the experiment, with the rats divided into eight groups. Four rats occupy a unit/cell of the cage, making it eight treatments replicated four times. The experiment was laid out in complete randomized design (CRD) and data were analyzed with one-way analysis of variance (ANOVA). The biogro treatments (treated on okra plants) were administered daily as it was included in the feed given for five days (acute toxicity test). On the termination of the experiment, all the rats were sacrificed, blood samples were taken for analysis and organs of interest were carefully removed through cervical dislocation for diagnosis, these include the liver and kidney for histopathological examination. At the end of the experiment it was observed that the treatment had no significant effect on both the blood parameter Packed Cell Volume (PCV), Red blood cell count (RBC), Haemoglobin (HB), White Blood Cell counts (WBC), Neutrophiles (NEUT), and also no damage was recorded on the liver and kidney. Hence, further experiment would still be conducted before the safety of the treatments could be recommended for use at the manufacturer recommended doze.

Key words: Biogro, wistar rats, histopathology, food safety

INTRODUCTION

Hematology and serum biochemical assessments are relevant tools in evaluating the physiological and pathological status of mammals and birds, as they provide information for the proper diagnosis of diseases, making a prognosis, evaluating the efficacy of instituted therapy, and toxicity of drugs and chemical substances (Stockham and Scott, 2008). Serum biochemical assessment helps to predict pathological processes in the vital internal organs of the body such as the liver, muscle, heart, pancreas and kidney (Stockham and Scott, 2008). It also helps to establish the presence or absence of disease of an organ, and determine the nature and extent of a disease process (static, progressive or regressive) by serial performance of laboratory tests of the internal organs. The hematological parameters of utmost clinical importance include the red blood cell (RBC) counts, packed cell volume (PCV), haemoglobin concentration (Hbc), mean corpuscular values, white blood cell counts and differential cell counts (Thrall and Weiser, 2002).

Justification

The use of agrochemicals or even plant hormones as fertilizing elements or for pest control is necessary so as to boost agricultural/horticultural production in Nigeria. The usual practice is to recommend "appropriate" doze due to observed increase in yield. However, there is the need to continue to monitor the residual effects of these agrochemicals or plant hormones so as to ensure they have no residual effect(s) or at least, that the residuals are within safe limits recommended by regulatory authorities such as WHO and FAO. Hence, our recommendations will no longer be based on quantity (yield) only but also on food quality. The objectives are: 1) To evaluate the kidney and liver of treated animal for effect of treatment and 2) To investigate the hematology effects on treated animals.

MATERIALS AND METHODS

This study was carried out at the animal experimental house, water hyacinth National Horticultural Research Institute Ibadan Oyo state, Clinical pathology laboratory, University of Ibadan and Histopathology laboratory of the Department of Veterinary Pathology, Faculty of Veterinary Medicine, and University of Ibadan, Nigeria.

A total of 32 wistar rats were used. The rats were divided into eight groups (treatments) with four rats occupying a unit/cell of the cage, making it eight treatments replicated four times and the rats were acclimatized for one week before commencement of treatments. Feed and water were given to the animals during acclimatization ad-libitum. The biogro treatments were administered daily as it was included in the feed given for five days (acute toxicity test). On the termination of the experiment, all the rats were sacrificed and organs of interest were carefully removed through cervical dislocation for diagnosis. These include the liver and kidney for histopathological examination. The experiment was laid out in completely randomized design (CRD) and data were analyzed with one-way analysis of variance (ANOVA), group means were compared for significance at 95% confidence level (P 0.05) by Duncan's Multiple Range Test (DMRT) from SAS 2003.

Haematological and serum biochemistry determinations were carried out following standard procedures. PCV was determined by the micro-haematocrit method (Thrall and Weiser, 2002), Hbc was determined by the cyanomethaemoglobin method (Higgins et al., 2008). RBC count and total leukocyte count (TLC) were carried out by the haemocytometer method (Thrall and Weiser, 2002), differential leukocyte count was done by making a blood smear on a clean glass slide and staining it following the Leishman technique. The different cells of the leukocytic series were enumerated by the battlement counting method (Thrall and Weiser, 2002). The mean corpuscular values – mean corpuscular volume (MCV), mean corpuscular haemoglobin (MCH) and mean corpuscular haemoglobin concentration (MCHC) – was calculated using the standard formulae (Coles). The fixed tissues of rats were dehydrated with progressively increasing concentrations of ethanol. The tissues were passed through xylene solution to clear the ethanol and facilitate molten paraffin wax infiltration (55°C). After that, they were embedded in a wax block. Paraffin sections of 6μm thickness were cut with the rotary microtome and placed on cleaned glass slides. Finally, the sections were stained with hematoxylin and eosin. The stained slides were examined using a light microscope where the photomicrographs of the tissue samples were recorded.

RESULTS AND DISCUSSION

Result on hematological parameters of male wistar rats

Results from this study revealed significant difference in the hematological parameter (Monocyte). However, no significant difference was recorded in the white blood cell from rats treated with biofart, biogro and control as seen in Table 1. Rats from the T7 recorded the highest mean value for packed cell volumes while the lowest mean value was obtained on treatment T1. The haemoglobin recorded from treatments and control also showed significant difference, with the highest mean value for haemoglobin recorded from T7 while the lowest was from T6. Like pack cell volume and heamoglobin, significant difference was observed in the red blood cell, platelet, neut and mono of all the rats. (Table 1).

Table 1. Effects of treatments on haematological parameters of wistar rat

Treatment	PVC (%)	HB (Gg/dl)	RBC ($x10^6/mm^3$)	WBC (cells/mm^3)	LYM ($x10^6/mm^3$)	NEUT ($x10^6/mm^3$)	MONO ($x10^6/mm^3$)
T1	34.33b	11.63de	5.57c	2538.33a	63.67ab	36.33a	1.00b
T2	42.00a	13.37abc	7.18ab	1996.73	77.00a	31.67ab	2.00a
T3	39.67ab	12.53cd	7.52a	2303.33a	76.00a	22.67c	1.67ab
T4	40.00a	14.27ab	7.52a	1683.33a	58.33b	27.00bc	1.00b
T5	38.67ab	12.93bcd	6.35abc	2320.03a	69.00ab	27.67bc	1.00b
T6	37.67ab	10.5e	6.08bc	1533.33a	69.00ab	30.00abc	1.00b
T7	42.33a	14.7a	7.12ab	2472.33a	26.33c	24.00c	1.33ab
T8	39.67ab	13.63abc	6.90abc	2873.33a	70.00ab	23.33c	1.00b

Means within the same column followed by the same letter(s) are not significantly different at $P < 0.05$ using DMRT
PCV= Packed Cell Volume, HB= Haemoglobin, WBC= White Blood Cell counts
RBC = Red blood cell count, NEUT= Neutrophiles, LYMPH= Lymphocytes, MONO = Monocytes

In the histopathological evaluation of the liver and kidney of rats treated with biogro showed no injury as there was no visible lesion observed neither was any severe damage in terms of necrosis observed in any of the organs of the treated animals and this is in agreement with the work of McCormack (2011). In the various treatments, the only observable change is an increased vascular congestion ranging from mild to moderate. The treatments do not have a structural change on the tubules and other anatomic structures in the kidney. The toxicity effects of treatments are not acute as the clinical symptoms did not manifest in test animals.

The histopathologic examination of the liver, and kidney of experimental rats adjudged the increase in serum enzymes observed in the same animals. Animals on test ingredient suffered little or no defect from the test substance and this was evidence on the results shown (Plate 1) as there were no major significant differences among the parameters and also it was within the standard given by WHO (The rat report http://www.ratfanclub.org/values.html.). Absence of lesion/damage observed in the visceral organ examined could probably be attributed to the absence of toxic substances in the test substances as reported by Rajashekher et al. (1993). It is obvious that, when diet contain toxic substances such as anti-nutrient or toxin contaminants, the effect always resulted in histopathological damage to the body organs, most especially liver, spleen and kidney (Tolleson et al., 1996; Ewuola et al., 2003; Ewuola et al., 2009).

CONCLUSION AND RECORMENDATION

The report above has shown that the treatments had no significant effect on the hematology and likewise histopathology of the sample organs and invariably on the health of the test animals hence, the safety of the treatments for use would be determined after further experiments to validate the initial findings.

ABSTRACT
Agrochemical stores and distributing warehouses were surveyed in Ilorin, Kwara State. Structured questionnaire was administered on agrochemicals on sale in open market, associated risks and knowledge of pesticides use. Seventeen active ingredients: Paraquat dichloride, Glyphosate, Permethrin + pyriproxyfen, Dimethylamine salt, Cypermethrin, Chloropyrifos, Dichlorvos, Lambda-cyhalothrin, 2,2-dichlorovinyl Dimethyl phosphate, Hexaconazole, Imidacloprid, Dimethoate, Nicosulfuron, Profenofos + cypermethrin, S-metolachlor, Carbendazim and Mancozeb were recorded but herbicides and insecticides dominated the stores. Toxicity analysis of active ingredients were based on recommendation of international standard organizations: Fairtrade, UTZ, FSC, RSB, SAN and Pesticide Action Network, Highly Hazardous Pesticide (PAN-HHP). The results showed that some active ingredients were not approved, while some others were not listed for agricultural use. Majority of respondences (60%) know purpose of agrochemicals, 55% identified its use in agriculture, however 65% lack knowledge of its preparation, although about 57% of them claimed to have previously use pesticides. About 49% lack knowledge of active ingredients in agrochemicals, only 38% know of recommended dosage in agrochemicals. About 44% lacks knowledge of danger pesticides posed to human and environment, however around 94% believe pesticides are hazardous. About 17% of respondences know nothing about food safety, while $\geq$50% of respondences lacks proper knowledge of food safety. About 80% of respondences know nothing about pesticides standards, 74.4% lack understanding of maximum residue limit in crops, 54.5% have no knowledge of health implication of agrochemical use and 72.3% know no any agency in Nigeria with mandate for standards and registration of pesticides.

Key words: Pesticides, toxicity, active ingredients, residue, standards, risk

INTRODUCTION
Pesticides are used in agriculture to protect crops against pests, when applied to food crops it can leave potentially harmful residues. They may interact with plant surfaces, be exposed to environmental factors; wind, sun and may be washed off during rainfall. Pesticide residues are the deposits of pesticide active ingredient, its metabolites or breakdown products present in some component of the environment after its application, spillage or dumping. The presence of pesticide residues is a concern for consumers because pesticides are known to have potential harmful effects to other non-targeted organisms than pests and diseases. Infants, children and adults are commonly exposed to pesticides by eating them on and in food and animals equally ingest such through feeds and mills. Pesticides are potentially toxic to humans and have been linked to a wide range of human health hazards, ranging from short term impacts such as headaches and nausea to chronic impacts like cancer, reproductive harm, and endocrine disruption. The rise in number of chemicals being introduced into agriculture and horticulture and their popularity in recent time have led to some concerns over the operator safety. There are standard organizations that certify and license agricultural products for safe or consumption and to fulfill international requirement for trade. These standard organizations' requirement is often benchmark with provision of international organizations: 4C Association, Fairtrade International, FSC, RSB, Sustainable Agriculture Network, UTZ etc. in Nigeria, this sector seems uncoordinated, lacking regulation and enforcement required for best practices and safety measures to avoid associated risks. The study surveyed agrochemicals commonly sold in open market in Kwara State, evaluated knowledge of agrochemical risk and determine their safety statuses.

MATERIALS AND METHODS
Survey of agrochemical stores, warehouses and trading facilities was conducted round Ilorin

metropolis. A structured questionnaire was administered to store owners, students (faculties of Agricultural Science, Life Sciences and Physical Sciences), University of Ilorin and Extension officers in Ministry of Agriculture and Rural Development Kwara State. The information was sought on the trade name, status of agrochemicals (herbicide, insecticide or fungicide), active ingredient(s) present in the pesticides and target crops. Questionnaire targeted final year students of the selected faculties. The information was subjected to benchmarks of the international standards organizations as related to toxicity, restriction status, and effect of such active ingredients on human, animal and environment, and Pesticide Action Network International list of Highly Hazardous Pesticide (PAN-HHP). The responses from the structured questionnaire were subjected to descriptive statistical analysis using SPSS.

RESULTS AND DISCUSSION

Survey of three major stores which deals with agrochemicals in Ilorin showed seventeen active ingredients that are common in open market; these are dominated by herbicides and insecticides with limited number of fungicides (Tables 1, 2 and 3).

Table 1. Active ingredients in agrochemical store I and targeted crop(s)

S/N	Status	Active ingredient(s)	Targeted crop(s)
1	Herbicide	Paraquat dichloride	Maize, weeds, cowpea, rubber, oil palm
2	Herbicide	Glyphosate	Grasses, weeds, woody shrubs
3	Herbicide	Permethrin + pyriproxyfen	Maize, weed
4	Herbicide	Dimethylamine salt	Maize, tomato, cotton, fruit trees
5	Insecticide	Cypermethrin	Smaller insects
6	Insecticide	Chloropyrifos	Vegetables, rice, soya beans, cocoa
7	Insecticide	Dichlorvos	Insect of vegetable, rice, yam, cowpea
8	Insecticide	Lambda-cyhalothrin	Insect pest in maize, vegetables, rice
9	Fungicide	Hexaconazole (systemic)	Pepper, vegetable
10	Fungicide	Imidacloprid	Pepper, water mellon, groundnut, cocoa
11	Fungicide	Dimethoate	Carrot, beans, groundnut

Table 2. Active ingredients in agrochemical store II and targeted crop(s)

S/N	Status	Active ingredient(s)	Targeted crop(s)
1	Herbicide	Glyphosate	Annual grass, sugar cane,
2	Herbicide	Paraquat dichloride	Non-selective, grasses, broad leaved weeds
3	Herbicide	S-metolachlor	Potato, yam, ground nut
4	Herbicide	Di-methylamine	Corn, weeds, sugarcane
5	Insecticide	Cypermethrin	Corn, tomato, cocoa, water melon
6	Insecticide	Dimethoate	Beans, ground nut
8	Fungicide	Mancozeb	Fruits, vegetable

Table 3. Active ingredients in agrochemical store III and targeted crop(s)

S/N	Status	Active ingredient(s)	Targeted crop(s)
1	Herbicide	2,4-dimehylamine salt	Rice, rubber, wheat, sugar cane
2	Herbicide	Nicosulfuron	Maize
3	Herbicide	Glyphosate	Sugar cane, weeds
4	Insecticide	2,2-dichlorovinyl Dimethyl phosphate	
5	Insecticide	Lambda cyhalothrin	Pineapple, carrot, orange, rice, beans
6	Insecticide	Profenofos + cypermethrin	Maize, cotton, orange
7	Insecticide	Cypermethrin	Carrot, cocoa, groundnut, onion
8	Fungicide	Imidacloprid	Pepper, ground nut, cocoa
9	Fungicide	Carbendazim	Fruit and vegetables

The hazard criteria of the active ingredients are grouped into: acute toxicity, long term health effects, environmental toxicity and international regulations (global pesticide-related conventions).

The pesticides grouping, hazard and toxicity status (Table 4) were the recommendations of The Globally Harmonized System of Classification and Labelling of Chemicals (GHS), World health organization (WHO) Recommended Classification of Pesticides by Hazard, International Agency for Research on Cancer (IARC), U.S. Environmental Protection Agency (U.S. EPA) and EU categorization of endocrine disruptors. The recommendation of these organizations was as benchmarked by Fairtrade International, FSC, RSB, SAN (Sustainable Agriculture Network) and UTZ.

The knowledge of agrochemical is known by 96% of respondents, 64.5% lack knowledge of preparation of agrochemicals and 56.8% of responses have used agrochemicals before. About 51.2% have known about active ingredients in agrochemicals, only 38.8% of respondents were aware of recommended dosage for agrochemicals and majority (87.8%) agreed to the dangers pose by agrochemical use, through wrong application, body contact, toxic compounds etc.

Around 83.5% have knowledge of agrochemicals getting into food and water, majority (83.3%) have knowledge of food safety as it relates to pesticides use on crops and pre – harvest intervals, this understanding varied with proper handling, preparation, preservation and storage of food. On the pesticides data base system, 80.3% of respondents have not heard about European Union pesticide database, 74.4% have no knowledge about the maximum residue limit for pesticides in crops and public knowledge on danger or health effect of agrochemical showed that 54.5% of respondents have not heard about it on radio. Majority (72.3%) do not know any agency in Nigeria responsible for developing standards and registration of pesticides, and there was significant difference ($P < 0.05$) in the response of the respondents, especially on the basis of the interactions of faculty with institution and faculty with level. However, of the respondents that claim to know the agencies in Nigeria, 51.6% choose NAFDAC, 9.7% (NDLEA), while 19.4%, 6.5% and 3.2% stated it is both NAFDAC and NDLEA, Pest & Produce Control Department and NESREA, SON, FADAMA & Farmers. There was significant difference ($P < 0.05$) in the response of the respondents, especially on the basis of the faculty.

The environment toxicity of paraquat dichloride is that it is highly toxic to birds/may cause severe effect (Lewis et al., 2018). Paraquat is rapidly but incompletely absorbed and then largely eliminated unchanged in urine within 12–24 h, the very high case fatality of paraquat is due to inherent toxicity and lack of effective treatments (Gawarammana and Buckley, 2011).

Ingesting small to medium amounts of paraquat can lead to fatal poisoning, lung scarring and the failure of multiple organs, which include heart and respiratory failure, kidney and liver failure. Ingesting large amounts of paraquat cause confusion, muscle weakness, seizures, difficulty breathing, fast heart rate and coma (Gotter, 2018).

Mensah et al. (2015) reported that glyphosate and its formulations may not only be considered as having genotoxic, cytotoxic or endocrine disrupting properties but a causative agent of reproduction abnormalities in both wildlife and humans. This active ingredient has been restricted, only be used under specific and defined conditions. It is also a probable carcinogenic substance to human and have environmental toxicity by been very persistent in water and sediments (IARC, 2018). Glyphosate provokes oxidative damage in liver and kidneys of mammals by disrupting mitochondrial metabolism, disrupt endocrine-signaling systems and residues from glyposhate may pose higher risks to the kidneys and liver, reproductive development impairment, Vandenberg et al., 2012).

Permethrin has some health risk when used at higher levels such as headaches, dizziness, nausea, shortness of breath, skin irritation and redness of eyes (Adam, 2013). An active ingredient called cypermethrin is an insecticide, approved for use to manage agricultural insect pests. It is however listed as highly hazardous pesticide in 2011 and 2019. It is classified as highly restricted use with mandatory risk specific mitigation measures (Lewis *et al*., 2018; PAN, 2019). The half-life of cypermethrin on the environment takes about 30days, soil microbes easily breaks it down because it has low potential to move in the soil, when cypermethrin ids used accordingly at the needed sites it poses little to no risk (US-EPA, 1997). Chloropyrifos classified as highly hazardous in 2011 and 2019, poses inhalation risk to human, high aquatic toxicity, highly toxic to bees (FOOTPRINT 2007), birds with aquatic pollinator and wildlife risk (Lewis et al, 2018). Dichlorvos breaks down rapidly in humid air, in water and soil, it takes longer time on wood when exposed to humans through food can be acutely toxic with typical cholinergic signs that is highly hazardous, dichlorvos is not teratogenic in mice and rats' half-lives of recovery is about 15days in human and 2 hours in rats (Arpad, 2007). Dichlorvos is a possible and probable carcinogen (IARC, 2018; US-EPA, 2018) with high aquatic toxicity, and highly toxic to honey bees and birds (EC, 2000, 2004, 2007, 2008).

Nicosulfuron is not co formulated with other active ingredients, toxicity of Nicosulfuron in rats includes acute dermal irritation and eye irritation (FAO/WHO, 2013). Profenofos+Cypermerthrin is as a co formulated organo phosphorous insecticide, studies have shown its toxicity levels on animal, plants and even the environment fate when this insecticide comes in contact with. Profenofos was evaluated by JMPR in 1990, 1992, 1994 & 1995. Toxicological, reviews was also conducted in 2007 when an ADI OF 0 to 0.03mg/kg bw and ARfD of 1mg/kg bw were established, profenofos is a clear liquid with weak odour, its solubility in water at 22 *C is 2.8mg/l at a PH of 6.9, profenofos is slowly absorbed in metabolized, it was major residue when crops are harvested several weeks after the last applications, its residues are not expected to occur in succeeding crops reviewed by JMPR health risk shows that profenofos is unlikely to present a public health concern.

Lambda-cyhalothrinis is to be phased out by year 2024 and with highly restricted use, only be use under specific condition and according to the Globally Harmonized System (GHS) it poses fatal risk to human if inhaled. This active ingredient also poses long term health effect as endocrine disruptor and as having reproductive toxicity (EC, 2009b), 2,2-dichlorovinyl Dimethyl phosphate is another insecticide that is not listed in the active ingredients database of EU. Dimethoate is classify as probable carcinogen and with reproductive toxicity according to Globally Harmonized System (US- EPA, 2000; 2004; 2007; 2018). It is potentially to be prohibited according to standard organization like FSC, RA, UTZ. It also has inhalation risk to human, highly toxic to honey bees, birds and with aquatic, pollinator and wildlife risk according to SAN (FAO/WHO, 2013).

CONCLUSION

The information gathered from respondents in this study showed that many of the agrochemicals in Ilorin open market have some level of restriction of use based on recommendation of international standard organizations, with proved risks to humans, animals and environment. Many of the respondents also lack the expected adequate and required knowledge of use, toxicity and restriction statuses. Enlightenment and awareness by regulatory agencies on agrochemical related and safety measures will be a good channel of orientation for the public.

Table 4. Pesticides hazardous nature and toxicity status

S/N	Active ingredient(s)	Status in EU database	Status in BCI/RA/FSC/4C/SAN/UTZ	Status in PAN-HHP
1	Paraquat dichloride	Not approved	Prohibited, to be face out by 2024 Fatal if inhaled/may cause severe effects Highly toxic to birds/may cause severe effect	Added to PAN-HHP list in 2011, 2019. Acute toxicity: Fatal if inhaled. Not yet formally listed but agreed by PIC
2	Glyphosate	Approved	May only be used under specific, defined conditions Probable carcinogenic	Added to PAN-HHP list in 2011,2014, 2019. Long term health effect: possible carcinogen. Environmental toxicity: very persistent in water/sediment.
3	Permethrin + pyriproxyfen	Approved	Prohibited, highly restricted/ restricted use/risk specific mitigation measures are mandatory Identified as hazardous, use with extreme caution Minimization of use Probable carcinogen Highly toxic to honey bees Aquatic risk, pollinator risk, wild life risk	Added to PAN-HHP list in 2011, 2019. Long term health effect: probable/likely carcinogen. Environmental toxicity: highly toxic to bees
4	Dimethylamine salt	Not listed	Not listed	Not listed
5	Cypermethrin	Approved	Highly restricted/restricted use, Risk specific mitigation measures are mandatory Highly aquatic toxicity Highly toxic to honey bees, aquatic risk, pollinator risk	Added to PAN-HHP list in 2011, 2019. Environmental toxicity: highly toxic to bees
6	Chloropyrifos	Not indicated	Potentially to be prohibited Highly restricted/ restricted use/risk specific mitigation measures are mandatory May only be used under specific condition/minimization of use Inhalation risk, high aquatic toxicity/ highly toxic to bees, birds, aquatic risk. Pollinator risk, wildlife risk	Added to PAN-HHP list in 2011, 2019 Environmental toxicity: highly toxic to bees
7	Dichlorvos	Not approved	Highly restricted/prohibited, to be phase out by 2024 May only be used under specific, defined condition Highly hazardous, fatal if inhaled. Highly aquatic toxicity/highly toxic to honey bees, birds	Added to PAN-HHP list in 2011, 2019. Acute toxicity: highly hazardous, fatal if inhaled. Long term health effect: possible carcinogen Environmental toxicity: highly toxic to bees
8	Lambda-cyhalothrin	Approved	Highly restricted/minimization of use/ may only be use under specific condition, to be phased out by 2024 Fatal if inhaled Endocrine disruptor, highly aquatic toxicity/highly toxic to honey bees/aquatic risk, pollinator risk	Added to PAN-HHP list in 2011, 2019. Acute toxicity: fatal if inhaled. Long term health effect: Endocrine disruptor, reproductive toxicity. Environmental toxicity: highly toxic to bees
9	Hexaconazole	Not approved	Not listed	Added to PAN-HHP list in 2011. Long term health effect: possible carcinogen. Environmental toxicity: very persistent in water, highly toxic to bees.
10	Imidacloprid	Approved	Restricted, prohibited with exception for certain pests in certain crops and region/minimization of use.	Added to PAN-HHP list in 2011, 2019. Environmental toxicity: highly toxic to bees

			Prohibited without exception/potentially prohibited May cause sever effects Highly toxic to honey bees, birds/Neonicotinoid/may cause severe effects	
11	Dimethoate	Not approved	Restricted, minimization of use/potentially to be prohibited Inhalation risk Highly toxic to honey bees/highly toxic to birds/aquatic risk, pollinator risk, wildlife risk	Added to PAN-HHP list in 2011, 2019. Long term health effect: probable carcinogen, Endocrine disruptor, reproductive toxicity. Environmental toxicity: highly toxic to bees

ABSTRACT

This study aimed at determining the degree of synthetic pesticides usage among cocoa farmers across some growing states in Nigeria with a view to improving the prevailing circumstances. Structured questionnaires were administered on cocoa farmers in Abia, Cross River and Edo States to determine and analyze their usage of pesticides in the course of production. Data were obtained on the types and frequency of usage of pesticides on the farmers' individual cocoa farms. Results obtained were subjected to statistical analysis with a view to drawing reasonable scientific inferences. Highest percentage of farmers in Bende (19.78%), Ikwuano (20.48%) and Umuahia North (28.13%) Local Government Areas (LGAs), all in Abia State, made use of Ultimax Plus/Ridomil Gold, Snipper/Combat and Ridomil Gold, respectively. Most of the farmers interviewed in Etung, Ikom, Boki and Obudu LGAs of Cross River State made use of Actara and Ridomil Gold pesticides on their farms. DDForce. Ultimax Plus and Actara gave highest usage frequency among farmers in Esan West and Owan West LGAs of Edo State. Also, most of the farmers (91.66-100%) in Cross River State made use of government approved pesticides on their cocoa farms, unlike those in Abia (46.90-60.23%) and Edo (28.57-57.90%). Continuous use of banned pesticides by some farmers in the study areas may be due to ignorance, perceived effectiveness, availability and affordability. Governments at all levels therefore need to further educate cocoa farmers on the health and economic implications of continuous use of pesticides not approved by the Federal Government.

Key words: Pesticides, cocoa, usage frequency, questionnaires

INTRODUCTION

Cacao, like many other economic crops, is faced with the challenges of pests and diseases across the regions where it is being grown. An estimated 30 to 80% loss due to diseases and pests has been recorded across various localities. The implication of this is that approximately $2 billion is lost annually by cocoa farmers across the globe to the problem of pests and diseases. These losses, no doubt, have impacts throughout the cocoa supply chain and are concentrated more on the already impoverished farmers (Akinfenwa, 2019).

In a bid to curb the devastating effects of pests/diseases, cocoa farmers have resorted to the use of synthetic pesticides (sometimes indiscriminately) across the growing communities mainly because of their quick, effective action. This has however led to the heavy pollution of plantation environments including the underground waters, nearby rivers/streams, and the disruption of the ecosystem (due to the non-selective nature of the chemicals). The problems of development of resistance by pests/pathogens, persistence of the chemicals, and the attendant health hazards on farmers as well as consumers of the crop and/or its by-products have also come to the fore (Daxl et al., 2004).

The discovery of high pesticide residue in crops, particularly cocoa beans exported from West Africa, has led to their rejection at the international market. In fact, the European Union (EU) had earlier given the Nigerian government June 16, 2016 deadline to put a management system in place to reduce pesticide contaminated food products the country exports to the region or face continued rejection of exports. This, no doubt, will bring great losses to the farmers, discourage the practice of agriculture and in the long run, impart negatively on the nation's economy (Nwaosu, 2015).

In view of the above, this study aims to determine the degree of synthetic pesticides usage by cocoa farmers across some growing states in Nigeria with a view to improving the prevailing circumstances.

MATERIALS AND METHODS

Structured questionnaires were administered on truly representative population sample of farmers in nine high cocoa producing Local Government Areas (LGAs) of three Southern Nigeria States: Abia

(Bende, Ikwuano, Umuahia North LGAs), Cross River (Boki, Etung, Ikom and Obudu LGAs) and Edo (Esan West and Owan West LGAs). Data were obtained on the types and frequency of usage of pesticides on the farmers' individual cocoa farms. The data obtained were subjected to statistical analysis with a view to drawing reasonable scientific inferences.

RESULTS AND DISCUSSION

The frequency of usage of pesticides on cacao in Abia State is as shown in Table 1. Data obtained from the structured questionnaires showed that farmers in Bende LGA often used up to eighteen (18) different pesticides on their cocoa farms, followed by those of Ikwuano (13), and Umuahia North (12). About 19.78% of farmers sampled in Bende used Ultimax Plus/ Ridomil Gold; 8.79% used Gamalin 20, while 7.69% used each of Blue Bolt, Actara, and Red Force pesticides (Table 1).

Table 1. Frequency of use of pesticides on cocoa in Abia State

LGA	Pesticide																	
	UT	RG	DDF	KN	BB	RF	ACT	FOH	BST	CYP	SNPC	TDM	GM	CDP	CUS	TMX	RUP	SFB
Bende	19.78	19.78	2.20	2.20	7.69	7.69	7.69	2.20	5.49	1.10	1.10	1.10	8.79	1.10	3.30	5.49	2.20	1.10
Ikwuano	18.07	15.66	4.82			16.87	4.82		3.61	2.41	20.48	3.61		1.20	1.20		6.02	1.20
Umuahia North	3.13	28.13	12.5	6.25		9.38	3.13	3.13		3.13			3.13		18.75		6.25	3.13

The highest proportion of farmers (20.48%) in Ikwuano used either Snipper or Combat chemicals on the farm, followed by those that used Ultimax (18.07%) and Red Force (16.87%). Very few percentage (1.20%) of farmers in this area were used to applying Copper sulphate, Champ DP and Safato/Sarosate (Table 1). Highest percentage (28.13%) of farmers in Umuahia North indicated their preference for Ridomil Gold. This was followed by those who preferred Copper Sulphate, while Cypermethrine, Gamalin 20 and Safato/Sarosate were the least used in the LGA (Table 1). The highest proportion of the farmers visited/interviewed in Abia State were used to the application of Ridomil Gold, Ultimax and Red Force pesticides on their cocoa farms, while the least figure (1.10%) was recorded against cocoa farmers that used Safato, Champ DP, Snipper/Combat and Cypermethrine (Table 1).

Frequency of pesticide usage on cocoa in Cross River State is as depicted in Table 2. A total of twelve pesticides were commonly used by farmers in the State. Only two pesticides were mostly applied on cocoa farms in Etung LGA, while about twelve were used in Boki. In Etung local government area, only Ridomil Gold (33.33%) and Actara (66.67%) were often applied on cocoa farms. This was clearly different from what obtained for the other LGAs in the State. Findings also showed that Actara (36.00%) and Ridomil Gold (32.00%) were mainly used by farmers in Ikom. These were followed by Funguran OH (12.00%), while Round up/Touch down, Cofresh and Proteus (4% each) were least used. The trend was similar for farmers in Boki and Obudu. Ultimax Plus, DDForce, Esiom and Safato (8.33% each), however, showed least farmer usage in the latter (Table 2).

Out of the thirteen pesticides often used on cocoa farms in Edo State, only three (Best, Proteus and Bush Fire) were not used in Owan West LGA. Ultimax, DDForce and Actara had the highest frequency of use (15.79% each) in the LGA. These were followed by Ridomil Gold, Funguran OH and Tackle (10.53% each), while Tricel, Cypermethrine and Termex had the least. DDForce (35.72%) and Ridomil Gold (21.43%) were however mostly used in Esan West. These were followed by Best (14.29%) and Tackle (14.29%), while Proteus (7.14%), like Bush Fire, gave the least frequency of usage in the local government (Table 3).

Table 2. Frequency of use of pesticides on cocoa in Cross River State

Figure 1 depict the percentages of pesticides usage on cocoa farms in Abia, Cross River and Edo States respectively. Findings from this study showed that 60.23% of the farmers sampled in Ikwuano LGA in Abia State, followed by those of Bende (59.34%) in the same State, used government approved chemicals on their farms. Contrary to what obtained for the duo, higher percentage of farmers (53.10%) in Umuahia North used unapproved (banned) pesticides on their cocoa farms (Figure 1).

Results obtained from Cross River State revealed that significantly high percentage (89.66-100%) of farmers applied government approved pesticides on their cocoa farms. Virtually all the farmers in Etung LGA (100%), followed by those of Ikom (96.00%) and Boki (89.66%) with the least percentage, used government approved chemicals (Table 3). But unlike what was observed in Cross River State, 28.57 and 57.90% of farmers in Esan West and Owan West LGAs of Edo State made use of government approved pesticides on their cocoa farms (Figure 1).

	Bende	Ikwuano	Umuahia North	Etung	Obudu	Ikom	Boki	Esan West	Owan West
	Abia			Cross River				Edo	
Government approved (%)	59.34	60.23	46.9	100	91.66	96	89.66	28.57	57.9
Not approved (%)	40.66	39.77	53.1	0	8.34	4	10.34	71.43	42.1

Figure 1: Percentage of usage of pesticides on cocoa Abia, Cross River and Edo States

The use of pesticides on farms has raised a lot of concerns about the safety of residues in cocoa beans, soils and water. This also portends a huge harm to humans and the environment (Denkyirah et al., 2016). Previous research conducted across six cocoa producing LGAs in Osun State revealed that Ridomil Gold pesticide had the highest frequency of usage among the farmers interviewed (Adeniyi et al., 2017). The discovery agrees with the findings of this research across the LGAs visited in Abia and Edo States (Tables 1 and 3). The pesticide, however, had the second-highest frequency of usage after Actara among the farmers visited in Cross River State (Table 2). The authors (Adeniyi et al., 2017) also discovered that most of the cocoa farmers in Osun State (about 74%) used government approved chemicals on their farms. This is in line with findings from this research among farmers in Cross River State where at least 81% of the respondents used government approved chemicals. However, contrary to the authors' findings, the percentages of banned pesticides used by farmers in Esan West (Edo State) and Umuahia North (Abia) were significantly higher than those of the government approved ones (Tables 1 and 3).

The higher number of pesticides used in some of the LGAs sampled compared with others across the States visited may be due to the level of the farmers' education. The continuous use of banned chemicals by some farmers interviewed across the States visited (even despite their knowledge of government approved ones) may be due to their perceived effectiveness in the control of cocoa pests/diseases, cost effectiveness/affordability, and ready availability. Inadequate information and appropriate registration of the agrochemicals also contribute significantly to this (Antwi-Agyakwa et al., 2015). The use of government approved pesticides by virtually all the farmers interviewed in Etung LGA (Cross River State), Ikot Ekpene and Ikono LGAs (Akwa Ibom State) may, however, be due to a better understanding of pesticides/pesticide hazard control, coupled with relative availability of the said pesticides as explained by Damalas and Koutroubas (2017) and Antwi-Agyakwa et al. (2015).

CONCLUSION AND RECOMMENDATION

The number/type of pesticides used on cocoa farms in the study areas varied with location and farmers' perceived effectiveness/availability of those chemicals. Farmers in Akwa Ibom and Cross River States impressively made use of government approved chemicals to control pests and diseases on their cocoa farms. This was a clear contrast to what obtained in Edo State. An average compliance was however noticed among farmers in Abia State. There is, therefore, an urgent need by government at all levels to further intensify efforts at educating cocoa farmers on the health and economic implications of continuous use of pesticides not approved by the federal government through its regulatory agency (Cocoa Research Institute of Nigeria) on their crop. They also need to be cautioned against an over-use of the recommended pesticides in order to forestall any undesirable long-term residue accumulation in their cocoa beans.

NITRATE IN FRUITS AND VEGETABLES: BLESSING OR CURSE TO HUMANITY

Ezeh, I. N. and *Baiyeri, K.P.

Department of Crop Science, University of Nigeria, Nsukka
*Corresponding author's e-mail: paul.baiyeri@unn.edu.ng

ABSTRACT

Recent global trend in crop production is organic and most people are turning to vegetarianism as a means of sustainable healthy living. A vegetarian's diet is rich in fruits and vegetables. Green leafy vegetables are foods that contain considerable amounts of nitrate, which can have both positive and negative effects on the human body. Nitrate potential carcinogenicity and toxicity have been proven, particularly after the reduction of nitrate to nitrite or just serving as a reactant with amines and/or amides in the formation of N-nitroso compounds, -N-nitrosamines and other nitrogen compounds, which may have high levels of nitrate. A point estimate of the daily intake to establish proper health risks that arise due to elevated levels of nitrate in fruits and vegetables need to be well researched in Nigeria, as nitrate may have high risk factor for health, during cultivation and storing of produces. A comprehensive reevaluation of food sources of nitrates and nitrites is appropriate. The strength of volumes of evidence linking the consumption of nitrate and nitrite containing plant parts to beneficial and harmful health effects support the consideration of these compounds as nutrients as well as toxins. There is a significant difference, considering possible production location and season, in the level of nitrate in certain types of green vegetables and fruits, according to researches from other parts of the world. The possible impact on human health, especially knowing that exposure to nitrate can be potentially higher for the vegetarian population should be closely monitored. The issues raised above are the major theme of this paper.

Key words: Human health, diet, nitrate, nitrite toxicity, vegetable safety, fruit safety

INTRODUCTION

Fruits and vegetables supply essential nutrients, as well as the notorious nitrate. Nitrates are a set of compounds that involve nitrogen and oxygen molecules. The nitrates found in human diets have had a bad reputation for more than half a century (Lundberg et al., 2018). In an unprecedented pattern, the concentration of nitrates in fruits and vegetables are exceeding the allowable limits worldwide (Petersen and Stroltze, 1999; Hord et al., 2009). This raises series of concern given that a direct correlation exists between the degree of toxicity of nitrate and daily intake (Uddin et al., 2021). In most Western countries, this has led to stringent regulations regarding the allowable levels of nitrate present in food sold in the open market and supermarkets. Prototypically, these regulations are based on the assumption that nitrate is overly harmful to human health. Concerns over nitrate intake originated from the fact that they are associated with some forms of cancer and methemoglobinemia throughout the world (Vickers, 2017). It is worthy to note that the nitrate, which enters into the body through fruits and vegetables, become a substance of concern if it exceeds its Acceptable Daily Intake (ADI) limit or toxicity level (Du et al., 2007). Approximately 11-41% of daily intake of nitrate enters the organism. The acceptable daily intake (ADI) for nitrate determined by the Scientific Committee on Food (SCF) in 1997 amounts to 0 to 3.7 mg/kg body weight/day, which is equivalent to 222 mg nitrate/day for an adult weighing 60 kg. Studies have shown that the average adult, on a daily basis, consumes approximately 400 g of various vegetables, from which it can be concluded that the average intake of nitrate is 157 mg/day (FAO/WHO, 2013).

Nitrates are not broken down by stomach acid. Dietary nitrates are essentially inert and acquire biological activity only with nitrate reduction to nitrite and then serving as a reactant with amines and/or amides in the formation of N-nitroso compounds (nitrosamines), some of which are known to be carcinogenic, teratogenic, and mutagenic. The main sites of reduction are in the saliva (nitrate to nitrite), and the stomach and blood vessels (nitrite to NO). As such, nitrate serves as a source, via successive reduction, for the production of nitrite and nitric oxide as well as other metabolic products. Nitrites are also produced endogenously through the oxidation of nitric oxide and through a reduction of nitrate by commensal bacteria in the mouth and gastrointestinal tract (Norman, 2009). Inarguably, constant unchecked intake creates a higher ground for the development of cancer of the stomach and esophagus (Roohparver et al., 2018; Ozdestan and Uren, 2010). Some studies have shown that a positive correlation exists between high nitrate consumption and gastric cancer in humans (Nowrouz et al., 2012).

On the other hand, several plausible health benefits and preventive effects of nitrate have also been reported. A substantial number of studies in health and hypertensive issues have shown that nitrate has beneficial cardiovascular effects, including lowering of blood pressure (Kerley et al., 2018; Machha and Schechter, 2012). Scientific evidence also suggests that having abundant vitamin C and polyphenol in fruits and vegetables facilitate the non-enzymatic reduction of toxic nitrite to beneficial nitric oxide, thereby reducing the chances of nitrite reacting with secondary amines forming nitrosamines (Erkekoglu and Baydar, 2010; Rocha et al., 2010). These evidence points at the inconsistencies found in global research efforts trying to assert or disband the adverse or beneficial effects of nitrate. As a result, the debate on risk or benefit of exposure to dietary nitrate has remained challenging and unresolved amongst scientists around the world.

NITRATE IN FRUITS AND VEGETABLES

Fruits and vegetables provide a substantial portion of nitrates in human nutritional regime. There is a significant difference in nitrate concentration present in different plant parts such as the root and tuber vegetables, fruit vegetables, and fruits (Uddin et al., 2021). Besides leafy vegetables that contain a substantial proportion of nitrate, studies have shown that other types of crops such as oilseeds, grains, tubers and nuts also contain high amount of nitrate (Gundimeda, 1993). Some studies have shown that leafy vegetables and fruits contain higher levels of nitrate and contribute to about 85% of the dietary intake of nitrates in a number of climes (Chetty et al., 2019; Bahadoran, 2016). The results of a Belgian research suggest that half of the daily intake of nitrate into the body is through vegetables, especially lettuce, and 20% is through water and water-based drinks (Temme, 2011). Significant nitrate intake by eating lettuce was also confirmed by another study conducted in Denmark, where samples of vegetables sampled in shopping centers were analyzed, and lettuce from the winter period contained more nitrate than lettuce from the summer period. High amounts of nitrate were found in dill (2.936 mg/kg), spinach (2.508 mg/kg), lettuce (2.167 mg/kg) and red beet (1.446 mg/kg) (Petersen, 1999). Nuñez de González (2015) in the USA found nitrate mean value contents to be conventional in broccoli (394 mg/kg), cabbage (418 mg/kg), celery (1496 mg/kg), lettuce (851 mg/kg) and spinach (2797 mg/kg). Zhong et al. (2002) in China reported that the mean nitrates level was higher in A. tuberosum Roth (5150 mg/kg), spinach (4259 mg/kg), intermediate in radish (1878 mg/kg) and Chinese cabbage (1740 mg/kg).

In our world today, nitrate pollution from chemical fertilizers, pesticide residue (PR) overload in vegetables, and microbiological contamination along the value chain have emerged as alarming public health issues (Chan, 2011). The application of excessive nitrogen fertilizers in fruit and vegetable production is one of the key factors for the accumulation of nitrates in fruits and vegetables (Fewtrell, 2004). However, the quantity of nitrate available in agricultural produces also depends on a number of factors, which vary greatly from region to region. Escobar-Gutierrez (2002) reported that lower levels of nitrate in fruits and vegetables result from high temperatures and longer sunshine periods. Amongst such influencing factors include: biological properties of crop, lighting conditions, soil properties, humidity, frequency of planting in the field, vegetation period, season of harvest, processing time, geographical region and fertilization (Parks et al., 2012; Rose et al., 2008; Correia, 2010). It is very important to remember that the consumption of fruits and vegetables is not the only route (though prime source) for nitrate to enter human body. Other probable sources of nitrate, such as drinking water, meat and other consumables should be checked before consumption.

CONCLUSION

From available data, it is obvious that the prime concern for nitrate rich diet is the endogenous formation of carcinogenic nitrosamines. The human sources of nitrate are mostly of natural origin: plants, animal and water. Vegetables and fruits are considered the first contributors to dietary nitrate, as such; there is the need to bear in mind that leafy

ISSN: 2814-0508

vegetables accumulate a significant portion of nitrate from nitrogen-based fertilizers. It is also noteworthy that prolonged and inefficient storage of produces, along with excessive use of chemical fertilizers and nitrate-polluted water, contribute to the elevated levels of nitrate in fruits and vegetables. Therefore, the intake of nitrate through fruits and vegetables could be considered safe for the consumers, when appropriate measures are deployed to limit excess nitrogen available for plant uptake.

The Nigerian populace could possibly be exposed to amounts of nitrate that endanger health. It is important to emphasize that for a complete assessment of nutrient loads to the body, it is necessary to carry out chemical analysis of vegetables and fruits, meat and meat products, and drinking water and water-based drinks as well.

In the academic community, a sustained research on nitrate level of vegetables is recommended and needed in order to resolve the lingering human safety controversies surrounding nitrate and nitrite in the diet, such as "dietary nitrate - good or bad?

ABSTRACT

An incubation study was conducted in the Cocoa Research Institute of Nigeria (CRIN) Laboratory to determine the amount of N released by different organic materials of plant origin at each stage of incubation. The amount and type of nitrogen (NO^-_3 - N and NH_4^+ - N) released by the materials were also monitored. There were four treatments [cocoa pod husk (CPHU), Cocoa pod husk ash (CPHA), Oil palm bunch ash (OPBA) and control] replicated three times making a total of twelve experimental units which were arranged in a completely randomized design (CRD). Fifty grams of soil (40g top soil + 10g of river sand) were passed through 2 mm sieve. The samples were weighed into 72 sterilized 50cl plastic cups and 0.5g of each organic material was added into the plastic cup corresponding to each row except for the control. Results indicated that, organic materials irrespective of types significantly ($p<0.05$) increased NO_3 – N; NH_4 – N and Total N mineralization in the soil throughout the periods of incubation. Cocoa pod husk ash consistently and significantly ($p<0.05$) released the highest amount of NO_3 – N throughout the incubation periods relative to the milled CPHU and OPBA except at 12weeks after incubation (WAI) respectively. All the organic materials under consideration except CPHU reached their respective peak release two months after treatment application. It is therefore recommended that any of these materials can be used as substitute for chemical fertilizers which are quite scarce, expensive and environmentally hazardous to soil health.

Key words: Mineralization, experimental units, oil palm bunch ash, incubated samples

INTRODUCTION

Many research studies in Nigeria have focused on the use of synthetic fertilizers Information are scarce on the less known but important organic sources. Furthermore, government efforts have been concentrated on the supply and manufacture of chemical fertilizers. It has been shown that total dependence on fertilizer as main supply of plant nutrients is not sustainable at the level of majority of the peasant and small holding farmers who produce 90% of food need in Nigeria. Similarly, several studies on the use of inorganic fertilizers across the country (Nigeria) show a number of limitations to their proper, effective and profitable use. Above all, the continuous use of inorganic fertilizers has led to degrading of physical properties of soils caused by low organic matter levels, increased soil acidity and nutrient imbalance (Ayeni, 2009; Shweta Shambhavi et al., 2017). The need to increase soil organic matter contents for sustainable usage of Nigerian agricultural soils (Ogunwale, 2002) coupled with the aforementioned problems have called for a shift from the use of inorganic fertilizers to organic fertilizers. However, the rates of mineralization and nutrient release patterns of farm wastes have not been adequately studied. This study was conducted to determine the rate of nitrogen release patterns of Cocoa pod husk (CPH) and Oil palm bunch ash (OPBA) using the amount of nutrients released as indices.

MATERIALS AND METHODS

An incubation study was conducted in the CRIN laboratory to determine the amount and types of nitrogen (NO^-_3 - N and NH_4^+ - N) released by various ash materials (CPHU, CPHA and OPBA) at each stage of incubation. There were four treatments namely Cocoa pod husk (CPHU), Cocoa pod husk ash (CPHA), Oil palm bunch ash (OPBA) and control replicated three times making a total of twelve experimental units which were arranged in a completely randomized design (CRD). Fifty grams of soil (40g top soil + 10g of river sand) were sieved through 2 mm sieve into 72 sterilized 50cl plastic cups and 0.5g of each material was added into the plastic cups corresponding to each row except for the control. The contents of each sterilized plastic cups were mixed thoroughly and allowed to remain on the laboratory bench at room temperature and monitored for sixteen weeks. Moistening was carried out twice weekly to keep the soil and the treatments in the sterilized plastic cup wet at 60% field capacity at all times. Three sterilized plastic cups were retrieved per row at zero (0); fourth (4th); eighth (8th); twelfth (12th), sixteenth (16th) and twentieth (20th) weeks after incubation (WAI) respectively to give six incubation periods. The contents were leached into 100ml volumetric flask using funnel fitted with Whitman 42 filter paper. The soils were analysed for their N, NO_3 – N and $NH4^+$ - N contents as described below:

Statistical Analysis

Data obtained were subjected to statistical analysis of variance (ANOVA) procedure and means were compared at 5% level of significance using GENSTAT package (GENSTAT, 2005).

RESULTS

Nitrogen release pattern during the periods of incubation.

The different amount of N (NO3 – N; NH4 –N and Total N) released over the twenty (20) weeks of incubation is presented in Figures 1-3.

(a) Nitrate Nitrogen (NO_3- N)

The NO_3 – N release pattern of the various ash materials during the incubation periods are presented in Figure 1. Comparable to the control, all the organic materials significantly ($p<0.05$) increased NO_3 – N mineralization in the soil throughout incubation periods. CPHA produced the highest amount of NO_3^- – N released into the soil throughout the period of incubation except at

Analysis of Incubated samples

The following analyses were carried out at the end of each incubation period. Mineralized total Nitrogen (N) was determined by Kjedahl method as follows: Incubated soil (5g) was placed in digestion tube and one Selenium tablet was dropped into it with 15ml of concentrated sulphuric acid added and placed in digestion chamber for two hours, after which distillation and titration were done to determine the total Nitrogen (N). The changes in pH at each stage of release was determined in water at a ratio of 1:2 (soil/water) using a pH meter with glass electrode as described by Jackson (1965).

12WAI. The NO_3^- – N released was consistently and significantly ($p<0.05$) increased by CPHA up till the 8thWAI and a sharp reduction in the amount of NO_3 – N released was noticed up to 12WAI with an increase at 16WAI. The least NO_3- N released was recorded at 20WAI. However, the amount was significantly higher than other organic materials and control respectively. Similar trends were observed at 16th and 20th WAI respectively with CPHA maintaining the lead. This was distantly followed by OPBA with CPHU. All the materials (CPHA; OPBA and Control) reached their peak release at the same time (two months after application) except CPHU. The order of NO_3 – N release into the soil in descending order during the first two months was: CPHA > OPBA > CPHU > CTRL (Fig.1). At 12WAI, CPHU recorded highest values in NO_3 – N and this was significantly better than CPHU, OPBA and control of NO_3 – N released into the soil. At 20WAI, the amount of NO_3 – N released by CPHU and OPBA were not significantly ($p<0.05$) different from each other.

(b) Ammonium N (NH4 – N) release pattern

Figure 2 shows the amount of NH_4 – N released by the organic materials during the five months of incubation. The NH^+_4 – N released by CPHU and OPBA are not statistically different from each other but are significantly different ($p < 0.05$) from the control at the zero (0) four (4) and twentieth weeks of incubation. However, CPHA released the highest amount of NH_4 - N into the soil solution during the same period. At two months (8WAI) of incubation, the amount of NH_4 – N released into the soil by all the ash materials were significantly higher ($p<0.05$) than the control with CPHA maintaining the lead while control produced the least NH_4 - N release, this was closely followed by OPBA and CPHU respectively. The mean differences were significant. Generally, the amount of NH_4 – N released into the soil filtrate by the organic materials dropped at the end of the eighth weeks of incubation (8WAI).

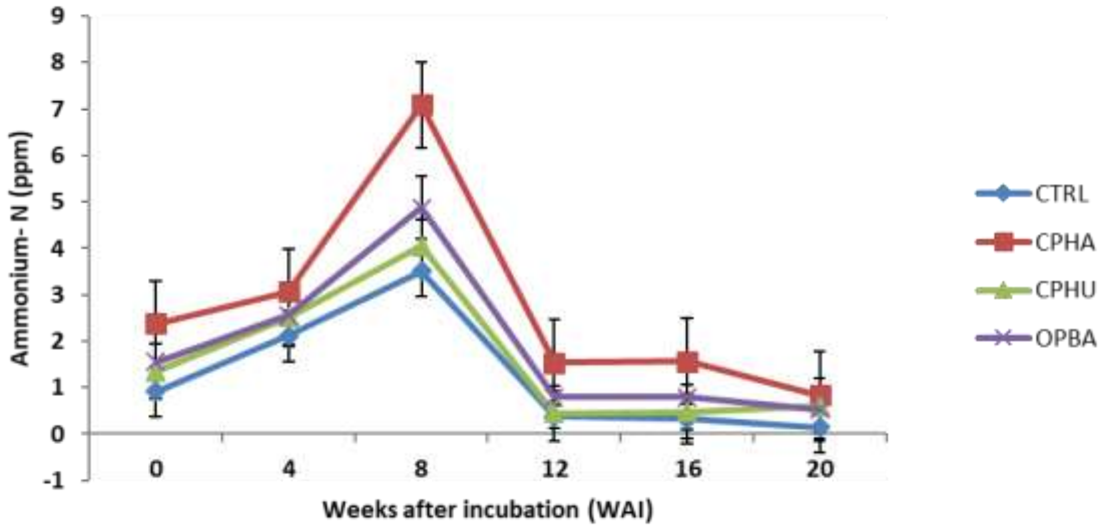

Figure 2. Effects of CPHA, CPHU and OPBA on Ammonium - N (NH4 - N) released (ppm) during the 20 weeks' incubation periods

CTRL= Control; CPH= Cocoa pod husk; CPHA= Cocoa pod husk ash; OPBA= Oil palm bunch ash

(c) Total N released pattern (N)

The total N released over 20 weeks of incubation is presented in Figure 3. The ash materials significantly ($p<0.05$) increased the total N released throughout the incubation periods. CPHA recorded the highest total N released into the soil. This was distantly followed by OPBA, while control recorded the lowest N release throughout the period. Generally, all the treatments reached their peak at the same time (8WAI) except CPHU which did at 16WAI after which the values decreased.

DISCUSSION

The incubation study revealed that application of CPH, CPHA and OPBA increased soil NO3- - N; NH4+ - N and total N. This finding was consistent with earlier incubation studies by Akanbi et al. (2014), Ogunlade (2008) and Ipinmoroti, (2006) that organic residues increased soil nutrients. Slower release of nutrient elements into the soil solution especially N from CPH compared to OPBA and CPHA based fertilizer was observed in this study. This was probably because the CPH materials would need to be decomposed by soil micro - organisms before the organic nutrients could be mineralized unlike CPHA and OPBA that have undergone process of burning such that the carbon building block had been broken and the organic nutrients are now in concentrated form. Hence, CPHA and OPBA fertilizer were quicker sources of N. The noticeable sharp increase(s) observed in all the organic fertilizer materials at 4th week of incubation led to an upsurge in the amount of various nutrient elements released into the soil. This might be probably due to the mineralization which must have taken place in the various soil media. Secondly, the marginal decrease in the amount of each of nutrient elements released at 12th weeks after incubation may have been that each material had attained the optimal release point hence, the stability after which the value dropped. Also, the differences in the periods of release by the organic materials as revealed by this study are an indication that each material mineralized at different rates. This probably might have been due to the differences in their carbon/Nitrogen (C: N) ratio. These observations were consistent with the results of incubation study of Akanbi et al. (2014).

CTRL= Control; CPH= Cocoa pod husk; CPHA= Cocoa pod husk ash; OPBA= Oil palm bunch ash

CONCLUSION AND RECOMMENDATION

Based on the significantly ($p < 0.05$) higher amount of nitrogen (N) released into the soil amended with organic wastes as a result of mineralization of the materials within the short periods of the incubation, it could, therefore, be concluded that CPHU, CPHA and OPBA can be used in soil amendment programme. However, application of these materials must be carried out two to four weeks before planting so that the young seedlings can benefit progressively from the released nutrients before reaching the peak at 8 weeks of application.

ABSTRACT

Cowpea is a major component of traditional cropping systems in many parts of the tropics and it is important because of its multiple uses in cooking, and industrial processing. Cowpea de-hulling is a long and tedious process which often involves manually detaching the cotyledon from the hull using hand–friction. The aim of this study was to design and construct a manual cowpea peeling machine to dehull soaked cowpea. The machine was designed and its performance was evaluated. The dehulling machine was made from stainless steel (for its anti- rust abilities) and wrought iron and was evaluated using three varieties of cowpea; white, mallam and oloyin. Machine efficiency was calculated for each variety and cost analysis carried out. Results showed that the dehuller's efficiency values ranged from 78%, to 82.35% for the three tested varieties, while output capacity of the machine was calculated to be 5.5kg/hr./batch. Machine performance showed that, effective threshing of different varieties of cowpea with minimum loss, improved threshing capacity, and efficiency were achieved resulting in good quality products across the three varieties. It was recommended that a cover should be provided to cover the hopper when it is not in use to prevent foreign materials from dropping into the machine.

Key words: cowpea, threshing, food processing, development, dehuller

INTRODUCTION

Cowpea (*Vigna unguiculata* L. Walp) is a major component of traditional cropping systems in many parts of the tropics and it is important because of its multiple uses. It is commonly called the '*hungry – season crop'* because it is the first crop to be harvested before cereal crops (Fawohunre and Olajide, 2020). Common uses of cowpea include soil fertility improvement through Biological Nitrogen Fixation, green manure, forage, production of high quality hay and silage, synthesis of nutritional products, suppression of weeds, food, and as a source of protein and income generation (Fawohunre and Olajide, 2020). Cowpea is one of the economically important indigenous African legume crops, especially in the dry regions covering 12.5 million hectares (Kebede et al*.*, 2020). In sub-Saharan Africa, cowpeas are produced mainly from West Africa, which accounts for 60% of worldwide production (Nkomo et al., 2021) with an estimated annual production of about 5.2 million tons. In Nigeria as well as most African countries, cowpea is eaten in various forms. It is also used in preparing a popular cowpea stew called gbegiri or kosei among the Yorubas and Hausas respectively (Babatunde, 1995). The protein in cowpea seed is rich in the amino acids, lysine and tryptophan compared to cereal grains. Cowpea can also be used at all stages of growth as a vegetable crop. Green cowpea seeds are boiled as a fresh vegetable, or may be canned or frozen, while the dry mature seeds are also suitable for boiling and canning (Fawohunre and Olajide, 2020).

In recent times, cowpea seeds are processed into packaged cowpea flour for further preparation into different food products. Cowpea dehulling is an integral part of bean processing. Olajide et al. (2019) defined de-hulling as the removal of seed coats (hull) which results in the separation of the cotyledon. Manual dehulling requires soaking the cowpea in water for 2 to 10 minutes, wherein the hulls absorb moisture and swell; thereby facilitating de-hulling by rubbing between one's palms, or beating with a wooden pestle and mortar, or grinding on stones (Aduba et. al., 2013). Housewives, small scale farmers, and food processors carry out these operations daily (Chukwu and Sunmonu, 2010), but it is an arduous task, especially when the cowpea to be manually dehulled is in large quantities (Olaoye and Olotu, 2015). Mechanical threshing involves high technology which is very expensive, and hence beyond the reach of Nigerian small – scale farmers though it helps to maintain the quality of the final products with minimum drudgery (Fawohunre and Olajide, 2020). The unstable electric power supply and high cost of fuel in the country are also deterrents to most peasant farmers. This limits the processing potential of the farmers. Hence, there is a need for a machine to circumvent these constraints at an affordable cost.

MATERIALS AND METHODS

Machine description and theoretical background

Machine design considerations hinged mainly around friction and bean transfer. De-hulling takes place through the process of the beans rubbing against each other and the separation chamber. Component parts and the fabricated cowpea dehulling machine are shown in Figures 1a, 1b, and 2, respectively. The major components of the cowpea threshing machine are: the hopper, dehulling chamber, outlet and frame. Materials used in the design of this cowpea peeler were carefully selected on the basis of properties such as power requirement, physical parameters of the cowpea, simplicity, stability, feed rate, speed of the drum, rigidity, bearings, durability, and strength of the materials, cost, and resistance to rust. The hopper is a stainless steel funnel shaped structure of length 260 mm, while the base measures 85 mm, and the upper collection part is 210 mm. The hopper is located above the dehulling chamber for easy feeding. The dehulling chamber consists of two cylindrical chambers. The internal chamber was made from wrought iron, and the outer de-hulling chamber was made from stainless steel and perforated to aid friction and bean de-hulling. The total length of the de-hulling chamber is 400 mm, while the diameter of the drum is 90 mm.

The stainless steel auger, which assists in the physical removal of cowpea skin through friction with the perforated drum, is primarily a transportation tool for the cowpea, moving beans from the de-hulling chamber to the outlet. The total length of the auger pipe is 380 mm and diameter of 480 mm. Two pillow bearings support the power shaft at both ends of the de-hulling chamber. Each of the bearing is held in position by 16mm bolts and nuts on top of the machine frame.

Dehulled beans and chaff fall and are collected through separate inclined outlets (30°) which facilitates the effective sliding of the grains. Dimensions of the outlet for de-hulled cowpea are 110 mm x 90 mm x 70 mm. The waste outlet measures 60 mm x 40 mm. The entire machine is mounted on a wrought- iron frame network of length 500.5 mm, while the lower and the upper base measures 300 mm and 200 mm respectively.

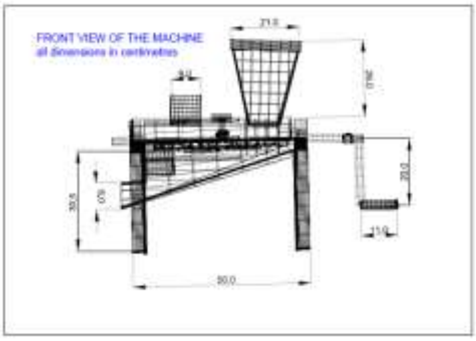

Figure 1a. Front view of the cowpea peeling machine

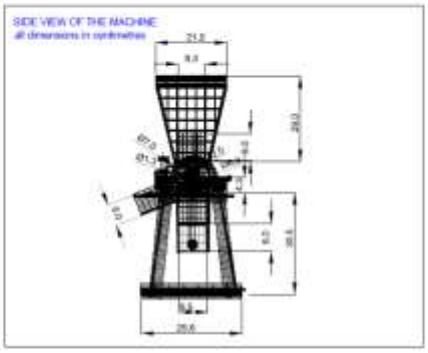

Figure 1b. Side view of the cowpea dehulling machine

ISSN: 2814-0508

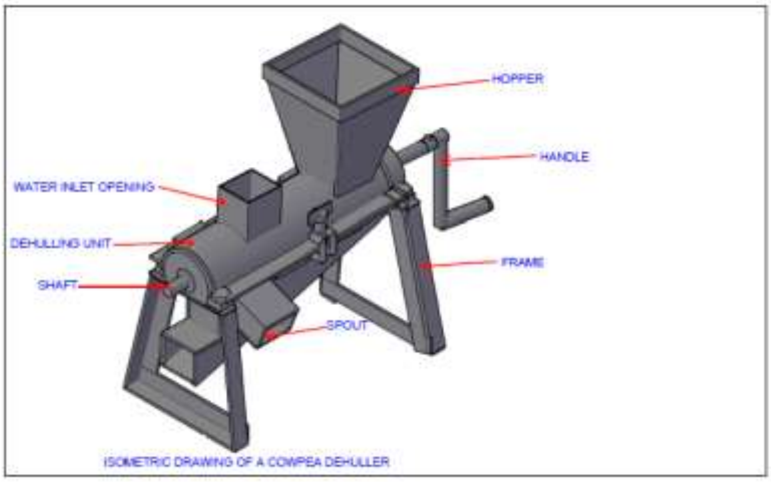

Figure 2. Isometric view of the cowpea peeling machine

Design considerations

1. Design of the dehulling unit: This was calculated using eqn. 1:

$V_{dc} = \pi r^2 h$ ….(1)

Where; V_{dc} = volume of the dehulling cylinder, r = radius of dehulling chamber, l = length of dehulling chamber

Volume of external dehulling chamber V_{dc} = 3.142 x 0.045^2 x 0. 0.00255 m^3

Volume of internal dehulling chamber (V_{idc}) = 3.142 x 0.040^2 x 0.38 = 0.00191 m3

2. Volume of cowpeas in dehulling chamber (V_c): The volume of cowpeas (Vc) in the dehulling chamber was obtained by subtracting the volume of the internal dehulling cylinder from that f the external one.

$Vc = V_{dc} – V_c$ = = 0.00255 – 0.00191 = 0.00064 m^3

3. Weight of cowpeas in dehulling chamber

Weight of cowpea (wc) = mg….. (3)

Where; m = mass of cowpeas, g = acceleration due to gravity

Also, m = ṗvc….. (4)

where; ṗ = bulk density of cowpea = 721 kg/m3 (Olajide *et al.,* 2019)., and Vc = volume of cowpea m^3

m = 721 x 0.000643 =0.461 kg/ 5 mins

Performance evaluation

The performance of the machine was evaluated using three different cowpea varieties; white, oloyin and *maalam.* 650g of each variety was soaked for five minutes and then poured into the hopper. The machine handle was turned to start de-hulling immediately and water was poured through the water inlet to avoid clogging of the de-hulling chamber. The process took a total of 10 minutes.

Machine efficiency was calculated using the formula:

$E= [(W_1-W_2)/W_1]$ x100

Where;

W1=Weight of de- hulled cowpea,

W2=Weight of cowpea un-hulled

and cost analysis carried out.

RESULTS AND DISCUSSION

The machine was observed to de-hull cowpea very effectively. Losses and breakages were found to be very negligible. Wet Weight changes were observed after de-hulling the cowpea. The cowpea de-huller removed the cowpea hull effectively.

Plate 1. Picture of the de-huller, de-hulled cowpea and chaff

Efficiency values ranged from 78% (for mallam bean) to 82.35% for white bean. This shows that the cowpea de-huller performed very well in de-hulling the three varieties of beans used. Operation time was between three to five minutes for total de-hulling.

Table 1. Performance evaluation results

Bean type	Weight of Cowpea (kg)				Efficiency
	Before de-hulling		After de-hulling		
	Dry weight	Wet weight	De-hulled bean weight	Chaff weight	
White bean	0.65	1	0.85	0.15	82%
Oloyin	0.65	1	0.85	0.15	82.35%
Maalam	0.65	1	0.7	0.15	78%

CONCLUSION AND RECOMMENDATION

A cowpea de-huller was designed, fabricated, tested and the performance evaluation was carried out. It was discovered that the quality of de-hulled cowpea increased with clearance between the hopper and the de-hulling chamber. The machine is highly efficient, economical, and stable, with highest efficiency rating of 82.35%.

ABSTRACT

Cashew is valued mainly by the nuts, which have been a major foreign exchange earner for many developing countries in the tropical and subtropical regions. Nearly 45% of world's cashew production comes from West Africa; Ivory Coast, Ghana and Nigeria being major producers. However, major factors limiting cashew productivity have been identified as low nut yield and nut weight. Cashew Polyclonal Seeds (PS) was sourced from Ghana through PROCashew-Nigeria project and Brazilian large (BL) biotype obtained at Ochaja substation of Cocoa Research Institute of Nigeria (CRIN). The planting materials were evaluated based on nut count, nut weight, kernel outturn, shelling %, growth performances and response to natural infection in the nursery. Nut count in PS had a mean of 145nuts while the BL was 119nut/kg. Both materials were of large nut sizes, although weight per nut was higher in BL (10.0g/nut) than 8.5g/nut recorded in PS. Seedling emergence was recorded on 12th day after planting in both materials but percent emergence varied. Percent germination in PS was 32.07% (2 weeks after planting) and 88.97% (4 weeks after planting), while the BL 55.46% (at 2 weeks) and 95.79% (at 4 weeks). The performances of BL were significantly higher in height (24.41cm and 29.34cm) at 4 and 6 weeks after planting respectively, while other growth parameters; girth, number of leaf, leaf area and branch varied with nursery period. Observations on disease infections showed no damping off of seedlings, however wrinkled leaves and leaf spot had greater incidence in PS but higher incidence of seedling dieback was recorded in BL. The BL at Ochaja substation of CRIN would compare as good material in selection for breeding except that records of yield, quality status of raw nuts and extensive genetic profiling of the materials are lacking.

Key words: Cashew, biotype, polyclonal seed, nursery, seedling performance, disease

INTRODUCTION

Cashew is a perennial tree crop, in family *Anacardiaceae*. Originated from North-Eastern Brazil and introduced into West Africa in the 16th century by the Portuguese settlers (Abdul and Peter, 2010). This crop is valued mainly by its article of trade which is the nuts, been a major foreign exchange earner for many developing countries in the tropical and subtropical regions. Around 45% of the world's cashew production comes from West Africa, which comprised of Ivory Coast, Ghana, and Nigeria being major producers (Monteiro et al., 2017). However, a prime factor identified to limit the productivity of cashew have been low nut yield and nut weight. (Adu-Gyamfi et al., 2019; Dadzie et al., 2014). This is also complicated by the new trend where nut weight is used as major criterion that determines the market value of raw cashew nuts in international trade. Low cashew productivity could be partly attributed to pest and diseases infestation, but high global demand for cashew nut from increasing world population, coupled with farmers request for varieties that provide high early yield per unit area with big nuts that can earn premium price suggest need for development of new varieties with high genetic potential for higher nut yield per unit area and improved nut quality (Gyamfi et. al., 2020).

MATERIALS AND METHODS

The PS was of Ghana origin, obtained through PROCashew-Nigeria project. The BL was obtained at Ochaja substation of Cocoa Research Institute of Nigeria (CRIN). Both planting materials were of the current year cashew fruiting season (2021). The moisture content of the raw cashew nuts (RCN) was determined, nut count, weight according to Lihong et al., (2014) and kernel outturn according Dieng et al., (2020). The RCN was sown in soil filled in a 20cm by 10cm polythene planting bags with one nut per bag. Routine nursery activities were carried out with cultural weeding and regular watering. Cashew seedlings were observed, data obtained on emergence, germination, height, girth, number of leaf, leaf area and branching were subjected to one – way ANOVA using SAS software package and the mean values were separated using Duncan Multiple Range Test (DMRT) at P≤0.05. Deviations/deformations in normal physiological growth of cashew parts were observed for symptoms and categorized according to Zhongrum and Masawe, (2014).

RESULTS AND DISCUSSION

The number of RCN in 1kg PS ranges from 144 – 147 nuts while BL had nut count of 117 – 121 nut/kg. The weight of BL and PS nuts showed that both belong to size of large cashew nut, however the weight per nut is higher in cashew BL (10.0g/nut) than 8.5g/nut recorded in PS (Table 1).

Table 1. Data on Brazilian large biotype and Polyclonal seed progenies cashew

Parameter	Polyclonal seed (PS)	Brazilian large (BL)
Source of planting material	Ghana/Tanzania	Ochaja, Nigeria
Nut count (average)	145	119
Nut weight (g)	7.0 – 8.5g	6.0g – 10.0g
Moisture content (%)	5.5 – 6.7%	8.0 – 10.0%
Outturn of RCN	48 – 56lbs	48 – 54lbs
Outturn of material at planting	47.5lbs	48.5lbs
Moisture of material at planting	5.5%	8.0%
Shelling percent (%)	34%	32%

The moisture content of RCN is directly proportion to the kernel output ratio (KOR)/outturn, which is a functional of storage. Decrease in moisture of RCN results into a reduction in outturn values, good storage enhances KOR but poor storage system brings down the kernel outturn. The outturn is important to processors, while shelling percent is one of major factor considered in materials aimed for a breeding program. The RCN of BL and PS were planted at moisture of 8.0%, KOR 48.5lbs and 5.5%, KOR 47.5lbs respectively (Table1).

Plate 1: Polyclonal seed progenies (A) Brazilian large biotype (B)

Emergence of RCN was observed on 12th day after planting (DAP) in BL and PS, with 23.53% and 10.34% respectively. Percent germination of PS was 32.07% at 2 weeks after planting (WAP) and 88.97% at 4WAP while BL recorded 55.46% at 2WAP and 95.79% at 4WAP. The percentage increase in germination from emergence to 4WAP was 11.62% and 24.56% in PS and BL respectively. While the percent increase in germination between 2WAP and 4WAP was 36.05% (PS) and 57.89% in BL (Table 2).

ISSN: 2814-0508

Table 3 showed the performances of BL and PS in the nursery. The height of BL was significantly higher (24.41cm) than 20.64cm recorded in PS at 4WAP. Significantly higher number of leaf and branch were also recorded in BL, while the girth and leaf area were the same in both PS and BL at 4WAP. At 6WAP, there was significant similar growth in girth, number of leaf, leaf area and branch with exception of height which was significantly higher (29.34cm) in BL compared to 25.30cm recorded in PS (Table 3).

Table 2. Emergence of Brazilian large biotype and Polyclonal seed progenies cashew

Parameter	Polyclonal seed (PS)	Brazilian large (BL)
Day of emergence	12DAP	12DAP
Percent emergence (%)	10.34%	23.53%
Number of foliar at germination	4 – 5 Leaves	4 – 6 leaves
Percent germination at 2WAP	32.07%	55.46%
Percent germination at 4WAP	88.97%	95.79%
Percent increase from emergence to 4WAP	11.62%	24.56%
Percent increase from 2WAP to 4WAP	36.05%	57.89%

*DAP (Day after planting), **WAP (Week after planting)

Table 3. Performance of Brazilian large biotype and Polyclonal seed progenies cashew

Cashew material	Height (cm)	Girth (mm)	Number of Leaf	Leaf area (m^2)	Branch
		4 Weeks After Planting			
Polyclonal seed (PS)	$20.64^b \pm 0.88$	$0.28^a \pm 0.02$	$7.73^b \pm 0.28$	$9.10^a \pm 1.40$	$0.00^b \pm 0.00$
Brazilian large (BL)	$24.41^a \pm 0.83$	$0.26^a \pm 0.02$	$9.27^a \pm 0.58$	$9.31^a + 0.84$	0.25s$\pm$0.33
		6 Weeks After Planting			
Polyclonal (PS)	$25.03^b \pm 1.23$	$0.31^a \pm 0.01$	$10.13^a \pm 0.56$	$44.60^a + 3.11$	$1.00^a \pm 0.68$
Brazilian large (BL)	$29.34^a \pm 1.06$	$0.34^a \pm 0.01$	$11.73^a + 0.72$	$44.97^a \pm 2.85$	$2.50^a \pm 0.55$

Natural infections with symptoms of physiological disorders common in nursery operations were assayed: wrinkled leaf, damping off, leaf spot and dieback. The seedlings recorded no incidence of damping off, however deviations from normal physiological growth were observed in varied degrees. Wrinkled leaf (Plate 2) was observed at 2WAP in 4.43% of PS and 2.67% BL, but incidence was not on the increase throughout the nursery period. Higher incidence (3.23%) of leaf spot (Plate 3) was recorded in PS to 1.78% in BL. Although dieback incidence (Plate 4) was minimal in both PS and BL, however higher (0.89%) in BL than 0.41% recorded in PS (Table 4).

Table 4. Physiological disorders in Brazilian large biotype and Polyclonal seed progenies cashew

Cashew material	Wrinkled leaf	Leaf spot	Damping off	Dieback	Survival count (%)
Polyclonal seed (PS)	4.43%	3.23%	0	0.41%	87.93%
Brazilian large (BL)	2.67%	1.78%	0	0.89%	95.79%

ABSTRACT

Fungal organisms are known to produce toxins which are deleterious to human health. Therefore, this study was conducted to isolate, identify and control with two plant lattices the filamentous isolates associated with four stored rice cultivars in Ishiagu, Ebonyi State, Nigeria. Four rice cultivars: - FARO-44, FARO-45, Local foreign and Chinyere were purchased from Eke Markets and were used for the study. Potato dextrose agar was used in isolating the fungi organisms in a completely randomized design and replicated three times. The collected data were subjected to Analysis of Variance and the significant means were separated using Tukey at P<0.05. The results revealed four fungi organisms which are Fusarium oxysporum, Magnaporthe oryzae, Aspergillus niger and Aspergillus flavus. The incidence of the organisms varies significantly from one isolate to others. Fusarium oxysporum (58.33%) had the highest percentage of occurrence while Aspergillus niger (8.33%) had the least. The percentage distribution of 66.11 %, 22.22 %, 25.00 % and 16.67 % were obtained for the Chinyere, FARO-45, Local foreign and FARO-44 respectively. Fusarium oxysporum (67.24%) had the highest mycelia inhibition with the J. curcas latex while A. niger (24.52%) had the least. Similarly, the latex of C. procera showed higher mycelia inhibition of 54.52% on F. oxysprum while Magnaporthe oryzae (20.98%) had the least. Therefore, this study recommended that seed health test should be carried out before sowing or planting in agricultural field.

Key words: Incidence, fungi, stored, rice, control and lattices

INTRODUCTION

Rice (*Oryza sativa,* L.) is a monocot plant with two main cultivated species *Oryza sativa* L. and *O. glaberrima* Steud, also respectively known as Asian and African rice (Khush et al., 2013). The crop is increasingly becoming an important staple food and cash crop in Africa (Tanko et al., 2016). In this continent, 15 million tons of rice is produced annually (Ronald et al., 2014). Africa most especially Nigeria were abundantly blessed with land and water resources that can support a huge expansion in rice production (Balasubramanian et al., 2007). Rice can be cultivated under diverse environmental conditions which may include and not limited to dryland, rainfed wetland, deepwater and mangrove swamps, and irrigated wetland (Balasubramanian et al., 2007). Seed is one of the three basic elements for crop production and help to increase agricultural productivity as it provides the maximum limit of crop yield for all other production inputs. Unlike fertilizers and pesticides, farmers cannot produce without seed (Miva et al., 2017). However, seeds carry pathogens such as fungi, bacteria, nematodes and viruses responsible for transmitting seed-borne diseases, which often cause partial or total crop losses (Barret et al., 2015). When seed has good physical, physiological, health and genetic qualities, farmers have greater prospects of producing a good crop (Miva et al., 2017). Plant latex is a natural plants polymer secreted by highly specialized cells known as laticifers (Hagel et al., 2008) and mainly flow inside laticifers including roots, stems, leaves and fruits of all flowering plants (Pickard, 2008). Studies have revealed the antimicrobial potential of latex-bearing plants. It is considered as analogous to animal venom because it contains cysteine proteases, which provide defense against herbivorous insects (Kitajima *et al.,* 2010) and phytopathogenic fungi (Souza et al., 2011). Similarly, both osmatin and thumatin proteins isolated from *Calatropis procera*, were found effective against fungi *Fusarium solani* and *Colletotricum gloeporiodes* (Larhsini et al., 1997). Similar activity is reported in *Pulmera rubra* and *Euphorbia tirucallai* latex proteins against phytopathogens (Souza et al., 2011). Though plant lattices have been used in controlling pant pathogens in certain crops, their efficacy in controlling seed-borne infections of fungal pathogens in rice seeds has not yet been critically evaluated. Therefore, the needs to: determine the incidence of seed borne fungi in stored rice seeds and the effects of the plant lattices on the mycelia growth of fungi.

MATERIALS AND METHODS

The experiments were conducted at the Plant Pathology Laboratory, Federal College of Agriculture, Ishiagu Ebonyi State, Nigeria.

Source of the rice cultivars and two plant lattices

The four rice cultivars (Chinyere, Local foreign, FARO-44 and FARO-45) were source from the local farmers in Ishiagu while Physic nut (*Jatropha curcas)* and Sodom apple (*Calaropis pricera)* latex were source from Amagu community, Ishiagu Ebonyi State, Nigeria

Sterilization of materials

Glass Petri dishes were surface sterilized in a hot air oven at 160 ^{o}C for 2 hours to ensure proper sterilization. Pair of forceps were also surface sterilized by dipping in 95% alcohol and flaming in red hot.

Preparation of potato dextrose agar (PDA)

The potato dextrose agar (PDA) was prepared by weighing 39 g of PDA powdered. This was poured into sterile distilled water (SDW) in a conical flask and make up to 1.0 litre. The flask was stirred gently to allow dispersion of the PDA powder in the added water. The PDA medium contained in the conical flask was plugged with cotton wool and covered with the aluminium foil paper which were later sterilized in an auto clave at 121^{o}C for 15 mins. The sterilized medium was subsequent allowed to cool to 45% and streptomycin at the rate of 20m/L were added and poured aseptically into 9 cm diameter Petri dishes covered and allowed to solidity.

Isolation of fungi from infected rice seed

Infected rice seeds were surface sterilized (1% NaOCl) for 1 min and rinsed in three changes of sterile distilled water), dried on sterile tissue paper and plated on 0.3 ml streptomycin amended PDA medium. Five replicate pieces from each of the infected seeds were plated on each plate. The plates were incubated at temperature of 28-30 ^{o}C for 5 days. Fungal growths associated with the infected seeds were observed and detailed structural features of each isolate were compared with those described in a standard manual of fungi (Barnett and Hunter, 1999).

Percentage (%) occurrence of fungus isolated

The percentage of occurrence of isolated fungi were calculated by multiplying fungi isolated with 10 and equally divided by the total number of fungi isolated.

Effects of plant lattices on fungal growth

Effect of plant lattices on mycelia growth with test fungi were done using food poisoning techniques (Sangoyomi, 2004) 1ml of each plant lattices were dispensed per Petri dish and 9ml of the media (PDA) were added to each of the Petri dishes containing latex and carefully spread evenly over the plate. These were used for the inhibition of mycelia growth. The plates were gently rotated to ensure even dispersion of the latex. The agar latex mixture was allowed to solidify and then inoculated at the center with a 4 mm diameter mycelia dice obtained from the colony edge of 5-day old pure cultures of test fungi. Each treatment consists of three replicates. The negative control sample consist blank agar plate (no latex) inoculated with the test fungi as described above. All the plates were incubated at 25^{o}C for 5 days and examined daily for growth and presence of inhibition. Colony diameter were taken as the mean growth along two directions on two predawn perpendicular lines on the reverse side of the plates. The effectiveness of the latex was expressed as percentage reduction of mycelial growth using the formula adopted from Egbontan et al. (2014):

$$M_p = \frac{M_1 - M_2}{M_1} \times 100$$

Where M_p is percentage reduction of mycelial growth, M_1 is mycelial growth in Petri dish and M_2 is mycelial growth in Petri dish containing latex.

Statistical design and Analysis

The experimental design was Completely Randomized Design (CRD) with three replications. Treatments means was subjected to analysis of variance (ANOVA) using Minitab Version 17 and the means separated using Tukey at $p \leq 0.05$.

RESULTS

Identification and percentage of occurrence of fungi isolates associated with stored rice seeds

The result of the study revealed that the fungi incidence on the stored rice seed in Ishiagu, Ebonyi State, Nigeria. The isolated fungi organisms were *Fusarium oxysporum, Magnaporthe oryzae, Aspergillus niger and Aspergillus flavus*. The incidence of the organisms varies significantly from one isolate to others. *Fusarium oxysporum* (58.33%) had the highest percentage of occurrence, followed by *Aspergillus flavus* (22.22%) while *Aspergillus niger* (8.33%) had the least (Figure 1).

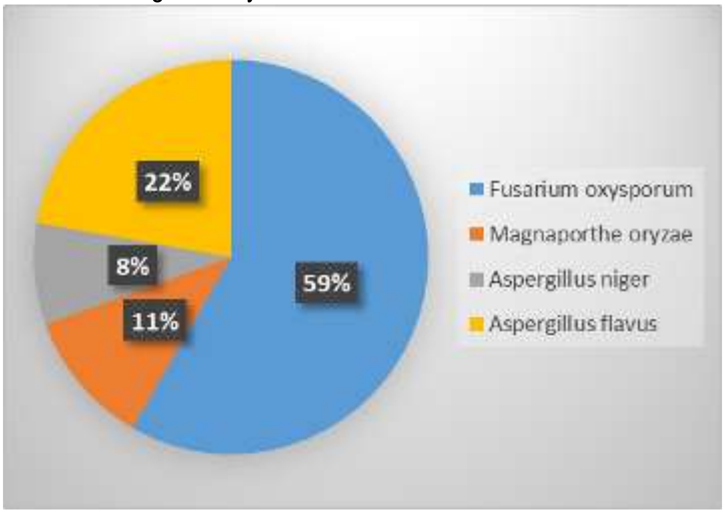

Figure 1. Percentage of occurrence of fungal isolates associated with stored rice seeds

Distribution of the fungi organisms isolated from four rice seed cultivars in storage

Table 1 showed the distribution of the fungi organisms isolated from four rice cultivars in storage. The percentage distribution of 66.11 %, 22.22 %, 25.00 % and 16.67 % were obtained for the FARO-44, FARO-45 and Local foreign respectively.

Table 1. Distribution of the fungi organisms isolated from four rice cultivars in storage

S/N	Rice cultivars	*Fusarium oxysporum* (n)	*Magnaporthe oryzae* (n)	*Aspergillus flavus* (n)	*Aspergillus niger* (n)	Distribution (%)
1	Chinyere	8	1	3	1	36.11
2	FARO-45	6	1	0	1	22.22
3	Local foreign	3	2	4	0	25.00
4	FARO-44	4	0	1	1	16.67

n= number of isolates

Effect of plant lattices on the mycelia growth of fungi isolates

Table 2 revealed the effects of two plant lattices on the mycelia growth of fungal isolates associated with rice seeds. The results showed a significant difference ($p > 0.05$) among the three isolates with the two plants lattices. *Fusarium oxysporum* (67.24%) had the highest mycelia inhibitive with the *J. curca*s latex followed by *Magnaporthe oryzae* (28 55%) while *Aspergillus niger* (24.52%) had the least. Similarly, the latex of *Calatropis procera* showed higher mycelia inhibition of 54.52% on *Fusarium oxysprum*, followed by *Aspergillus niger* (22.22%) while *Magnaporthe oryzae* (20.98%) had the least.

Table 2. Effect of plant lattices on the mycelia growth of fungi isolates

Isolates	*Jatropha curcas*	*Calatropis procera*
Magnaporthe oryzae	28.55^b	20.98^b
Aspergillus niger	24.52^b	22.22^b
Fusarium oxysporum	67.24^a	54.52^a
Means	40.10	32.57
Standard error	7.34	5.92
Coefficient of variation (%)	54.92	54.53

Means that do not share a letter are significantly different at P≤ 0.05 using Turkey.

DISCUSSION

The present study revealed four fungi isolated belonging to three genera that were associated with farmers stored rice seeds in previously harvested rice seeds in Ishiagu. The fungal isolates were *F. oxysporum, A. niger, A. flavus and M. oryzae*. Bhuiyan et al. (2103) revealed that a total of seven seedborne fungi were associated with forty rice seed samples. Furthermore, Bhuiyan et al. (2103) reported that the isolated fungus were *Bipolaris oryzae, Alternaria padwicku, Sarocladinum oryzae, Currularia lunata, Aspergillus niger*. Similarly, Yekini and Afolabi (2020) stated that *F. oxysporum, C. lunata, M. oryzae, A. niger, Sclerotium oryzae and Penicillium* species were associated with rice seeds. Moreover, the effect of *J. curcas* and *C. procera* latex on the mycelia growth of the tested isolated showed that a positive response in reducing their growth. Kitajma et al. (2010) stated that plant telex is considered as analogous to animal venom because it contains cysteine proteers which provide defense against herbivores insects. Lartex from *Hancornia* species (Apocynaceae) has shown activity against *Klebsiella, Pantoea, Enterobacter and Burkholderia* (Silva et al., 2011), while *Heven brasilensis* latex shows antifungal activity *Trichosporum cutaneum and Cryptococus neoformaus* (Giordani et al., 1991).

CONCLUSION

In conclusion, the present study revealed *F. oxysporum, M. oxyzae, A. niger and A. flavus* as seed borne fungal isolates associated with stored rice seed in Ishiagu. The study also revealed the different level of occurrence of each isolates on the five rice varieties. Likewise, the present study reveals the effect of two plant lattices; *J. curcas* and *C. procera* on the mycelia inhibition of the isolates which is worth note.

RECOMMENDATION

This study, therefore, recommended that seed health test should be carried out before sowing or planting in agricultural field. Moreover, the stakeholder should set up a modality to educate and trained rice farmers on seed testing before sowing. Pathogenicity of the isolates should be conducted to determine the casual organisms of the symptoms. The two plant lattices should also be further tested on other fungal isolates and *in-vivo*.

ABSTRACT

Storage filamentous fungi (moulds) are a form of fungal pathogens which cause major spoilage of stored cocoa beans and other foods/animal feeds. The beans are susceptible to fungal spoilage during and after fermentation. Contamination of the commodity by storage fungi of the Aspergillus, Penicillium and Fusarium genera often results in the production of secondary metabolites known as mycotoxins within the commodity. They include aflatoxin (AFs), ochratoxin A (OTA), zearalenone, trichothecenes and fumonisins, and are of high occurrence and toxicity. Mycotoxin contamination of cocoa beans and other stored food/plant materials has remained a threat to human as well as animal health and existence. Consumption of such food results in some carcinogenic, teratogenic, immune suppressive, or estrogenic effects in the human body, coupled with serious economic losses. Mycotoxins particularly target vital organs (the liver, kidney) of the body and the nervous as well as immune systems. Protection of consumers from the risks of mycotoxin contamination of stored cocoa beans and other foods has as a result, become pertinent. Practical steps must therefore be taken by experts towards effective control of mycotoxin production in stored products. Contamination reduction interventions/protocols are of great importance in resolving this impasse.

Key words: Mycotoxins, cocoa beans, storage moulds, contamination

INTRODUCTION

Fungi are ubiquitous pathogens that are major spoilage agents of foods and feedstuffs. The infection of plants by various fungi not only results in low crop yield and quality with sufficient economic losses but also causes contamination of grains with poisonous fungal secondary metabolites called mycotoxins. Cocoa is one of the important ingredients in several kinds of foods, such as cakes, biscuits, child-foods, ice creams and sweet consumed in developed countries. Cocoa beans originating as seeds in food pods of the tree *Theobroma cacao* are a source of cocoa powder. Neither storage nor processing conditions of cocoa are strictly controlled in most tropical countries Fungi contamination is therefore possible at many critical points in cocoa production chain (Magan and Aldred, 2005).

Cocoa beans are susceptible to fungal spoilage during and after fermentation. Filamentous fugal species (moulds) belonging to the genera *Aspergillus, Mucor, Penicillium* and *Rhizopus* are of great importance in this regard. Recently, *Aspergillus* species were the most frequently isolated fungi from samples of ground cocoa based beverage (Oyetunji, 2006). Furthermore, many fungi perticularly from the genera *Aspergillus* and *penicillum* produce mycotoxins that cause acute or chronic intoxication and damage to humans and animals after ingestion of contaminated food and feed. (Brera et al., 2005). Among the mycotoxins, aflatoxin (AFs) and ochratoxin A (OTA) are of special interest given high occurrence and toxicity. Aflatoxins are hepatoxic, teratogenic, mutagenic and carcinogenic mycotoxins produced by members of *Aspergillus* mainly *A. flavus* and *A. parasiticus.* The most potent of the four naturally occurring AFs (B_1, B_2, G_1 and G_2 is aflatoxin B_1 (AFB_1) (Horn 2007).

Beside AFs, some *Aspergillus flavus* strains, together with strains belonging to the species *Aspergillus tamari* also included in the section *flavi,* are reported to produce cyclopiazonic acid (Horn 2007). This mycotoxin is a specific inhibitor of calcium dependent ATpase which is toxic to animals and humans (Abouzied *et al.,* 2002). Ochratoxin A (OTA) is mainly a mycotoxin with nephrotoxic effect and has been associated with Balkan Endemic Nephropathy (Abouzied et al., 2002).

The quality of cocoa beans is highly dependent on processing technologies and storage conditions for preventing the defective quality. Furthermore, storage and processing conditions of raw cocoa in the producing countries are not very safe and mycotoxigenic fungi contamination may be possible at many critical points of the producing chain.

Drying limits mould growth during transportation, and storage reduce raw cocoa bean moisture content from 60 to 8%. Exposure of raw cocoa to high moisture levels is most likely to occur at stages between postharvest and final consumption. Inefficient drying systems can also lead to fungal activity. Fungal spoilage of crops will depend on cultivation, harvesting, handling, transport, and post-harvest storage and marketing conditions. Fungal activity can result in contamination with mycotoxins and could pose a health risk to the consumers. So, it is important to identify fungal contaminants in raw cocoa beans because some moulds can grow and produce mycotoxins on these commodities while certain moulds can cause infections or allergies.

Mycotoxins are toxic compounds that are naturally produced by certain types of filamentous fungi (moulds). Moulds that can produce mycotoxins grow on numerous foodstuffs such as cereals and dried fruits such as cocoa, nuts, and spices. Mould growth can occur either before harvest or after harvest, during storage, on the food itself often under warm, damp and humid conditions. Most mycotoxins are chemically stable and survive food processing. The following fungi (namely: *Aspergillus niger, A. flavus, Botryodiplodia theobromae, Fusarium* spp., *Mucor* spp., *Neurospora* spp., *Penicillium* spp., and *Phytophthora palmivora.*), were consistently isolated from mouldy cocoa bean samples. All these fungi were isolated using different methods such as washing, direct and dilution plate methods (Bhat et al., 2010).

CONDITIONS THAT ENCOURAGE PRODUCTION OF MYCOTOXINS

Mycotoxins can be synthesized under suitable biological, chemical and physiological conditions. Production of toxin is influenced by some ecological and environmental factors such as temperature, type of substrate, moisture content, relative humidity, water activity, occurrence with other fungi, physical damage by insects, use of fungicides, and storage condition. Due to the high temperature and humidity conditions in tropical and subtropical regions, high presence of mycotoxins can be expected (Bhat et al., 2010).

Stored crops under temperatures (28 to 31 ◦C), and high relative humidity (50% to 60% and 70% to 80% during the dry and wet seasons, respectively) conditions can easily be contaminated by mycotoxin-producing fungi. Other factors such as poor harvesting practices, improper processing, packaging, drying techniques, and transport activities influence fungal growth and increase the risk of mycotoxin production (Bhat et al., 2010). Climate changes seem to be another important factor affecting mycotoxin contamination of foods and feedstuffs (Paterson and Lima, 2010). Depending on the geographical and climate conditions, different fungal species can infect foods and feedstuffs. *Aspergillus, Penicillium,* and *Fusarium* species are the most important mycotoxin producers. *Penicillium* and *Aspergillus* species can grow at higher temperature and lower water activity than *Fusarium*. *Fusarium* species grow well at higher water activity and lower temperature. *Aspergillus* species can be found on nuts, cereals, palm kernels, cocoa, and coffee beans (Bhat et al., 2010).

IMPACTS OF MYCOTOXINS ON MAN'S WELL-BEING

Mycotoxin contamination of foodstuffs is a worldwide problem and a major health threat for humans and animals that cause significant economic losses in both developing and developed countries. Mycotoxin contaminations of agricultural crops pose significant economic losses to both crop producers and handlers who have to give market discounts for the contaminated products. In cases of severely contaminated crops, they have to dispose of the product.

Other economic losses related to mycotoxin contamination of foodstuffs are loss of business and product recall. Cereals (wheat, rice, maize, and sorghum), oilseed (sunflower, peanut, cottonseed, and soybean), spices (black pepper, chillies, turmeric, coriander, and ginger), tree nuts (pistachio, almond, coconut, and walnut) are the most important agricultural commodities that can be contaminated with mycotoxins. Mycotoxins may be inhaled, ingested or absorbed through the skin. No matter how mycotoxins enter the body system, they can cause sickness, lower performance, or death in both animals and humans (Bankole and Adebanjo 2004). Mycotoxicosis is the consequence of

ISSN: 2814-0508

ingesting mycotoxin-contaminated food or feed by higher animals. Consumption of mycotoxin-contaminated food or feed results in acute or chronic consequences such as carcinogenic, teratogenic, immune suppressive, or estrogenic effects. Common symptoms of mycotoxicosis in human are diarrhea, vomiting, and gastrointestinal problems (Bhat *et al.,* 2010).

DIFFERENT TOXINS PRODUCED

Aflatoxins (AFs)

Aflatoxins are primarily hepatotoxic and they are also secondary metabolites produced by some members of the *Aspergillus* genus. Aflatoxins are difuranocoumarin derivatives, which are produced by *Aspergillus flavus* and *Aspergillus parasiticus* which are highly toxic, carcinogenic, immunosuppressive, teratogenic, and mutagenic compounds. Aflatoxins are usually found in agricultural products such as cereals (rice, wheat, maize, barley, and sorghum), spices (black pepper, chili, ginger, coriander, and turmeric), and fat-containing crops including tree nuts (pistachios, almonds, walnuts, and Brazil nuts), peanuts, and oilseeds (cotton, sunflower, sesame, and soybean). The negative effects of Aflatoxin(AFs) have been linked to kwashiorkor, low levels of secretory immunoglobulin A (IgA), loss of weight among children (Bhat et al., 2010). They were also found in the tissues of patients suffering from Reye's syndrome that is characterized by encephalopathy and visceral deterioration. Patients suffering from Reye's syndrome show kidney and liver enlargement and cerebral edema (Zain, 2010)

Ochratoxin (OTA)

Ochratoxin is the second most important mycotoxin. Ochratoxin A is the major mycotoxin of this group which is usually produced by *Aspergillus ochraceus* and *Penicillum verracosum* (CAST, 2003). Other fungi like *Asppergillus niger* group may be important in some commodities (Tjamos et al., 2004). Ochratoxin has been regarded as being produced in storage conditions which favor mold growth and toxin production. Grains that have musty odor should be suspect for mycotoxins and ochratoxin (CAST, 2003). Human exposure to OTA usually occurs through the consumption of improperly stored food products. OTA can be determined in the tissues and organs of humans and animals (including breast milk, meat, and blood). The adverse effects and toxicity of ochratoxin show that is a liver toxin, and tumors of the upper urinary tract have been associated with exposure to ochratoxin. Ochratoxin induces apoptosis in human lymphocytes and neuronal cells. Induction of apoptosis in neuronal cells contributes to the pathogenesis of neurodegenerative diseases. In a human, ochratoxin is distributed through the blood mainly to the kidneys, but in animals, it has been shown to be accumulated in body organs and tissues such as meat, liver, and kidney. Evidence has shown that exposure to OTA can cause problems for kidneys (functional and morphological changes) and some harmful effects on the liver and heart. Furthermore, OTA can cause morphological abnormalities, gastrointestinal/renal tissue lesions, lymphoid tissue lesions, blood clotting, and reduction in egg production (Bhat et al., 2010).

Zearalenone (ZEN)

This mycotoxin co-exists with deoxynivalenol (DON) as the same organism *Fusarium graminearum* or *Fusariumculmorun*. Chemically, it'sa phenolic resorcyclic acid lactone that is estrogenic when consumed by animals (CAST, 2003). The adverse effects of zearalenonne (ZEN) can cause infertility, abortion, reproduction problems (especially in swine), and is associated with cervical cancer. ZEN has the ability to disrupt sex steroid hormone functions and its metabolite. ZEN and its metabolites bind to estrogen receptors and activate gene transcription. Besides, they interfere with the regular activity of the endocrine glands (Bhat et al., 2010).

Trichothecenes

Trichothecenes are produced by *Fusarium* spp. These includes DON, T-2 toxin, diacetoxyscirpenol, and nivalenol (Glenn, 2007). Trichothecenes are produced by several fungal genera such as *Fusarium, Trichoderma, Myrothecium, Stachybotrys, Trichotecium,* and Phomopsis. Trichothecenes inhibit DNA and protein syntheses, but no mutagenic or carcinogenic effect has been reported. The main target affected by trichothecenes is the digestive system. DON and T-2 toxin affect immunity by inhibiting protein synthesis and cell proliferation. DON decreases antibody and immunoglobulin levels in the body (Bhat et al., 2010).

Fumonisins (FMNs)

Fumonisins are one of the main mycotoxin classes of concern produced by *Fusarium species* (Glenn, 2007). *Fusarium species* are able to cause seedling diseases, stalk rots, ear rots, root rots, and kernel damage. FMNs have been found in several agricultural products including corn products, medicinal plants, herbal tea, dried figs, and bovine milk. There is not enough evidence for human health hazard related to FMN contaminated food, the chronic effects of FMN is in animals which include impairment in the basic immune function, kidney and liver damage, respiratory difficulties, heart problems, reduction in milk production, weight reduction, and increase in mortality rate. Another sign of FMN toxicosis in dairy cattle included elevated serum enzyme activity of diagnostic liver enzymes that show mild hepatocellular injury (Moretti et al., 2010).

CONCLUSION

Mycotoxins are microbial secondary metabolites often produced by moulds of the *Aspergillus, Penicillium* and *Fusarium* genera. Mycotoxin contamination of cocoa beans and other stored food/plant materials has remained a threat to human as well as animal health and existence. They are carcinogenic, and negatively affect vital organs like the kidney, liver, as well as the nervous and immune systems of the body. Zearalenone is capable of causing hormonal dysfunction, abortion, infertility and other reproduction problems (especially in swine). In order to protect consumers from the risks of mycotoxin contamination of stored cocoa beans and other foods, maximum permissible levels have to be generated and subjected to control by regulatory body. Practical and more proactive steps however need to be taken by experts towards the control and mitigation of mycotoxins at storage. Intervention and reduction protocols for contamination in food commodities are also needed.

ABSTRACT

Leaf samples of Raphinus sativus were collected and subjected to routine laboratory studies to determine the incidence and severity of fusarium wilt of radish from two environments (open field and high tunnel) in Nsukka, Enugu State of Nigeria. The study was carried out between March and May 2018. Thirty leaves were sampled in each environment and the samples taken using two longitudinal transepts. Result obtained from the laboratory analysis showed the presence of Fusarium oxysporum the causative organism of fusarium wilt of radish. The disease incidence was high with 57% and 70% at 2 and 3 weeks after planting respectively. Disease severity records showed 34.7% and 38.3% at 2 and 3 WAP respectively. Significantly high incidence of fusarium wilt were recorded in open field (43.3%) compared to high tunnel (16.7%), while the disease severity in open field was higher with 26.7% compared to high tunnel showing 5% severity at 3 weeks after planting.

Key words: Radish, disease, fusarium, environment, incidence, severity.

INTRODUCTION

Radish (*Raphinus sativus* L.) belongs to the family Brassicaceae, a popular root vegetable in both tropical and temperate regions. It is an edible plant, with a globular root that has a bright pink external layer and a white pulp. The root of this plant is the part consumed. One of the unique features of this plant is its short cycle, of approximately 30 days, which permits rapid gains of working capital (Rodrigues et al., 2013). *Raphanus sativus* is originally from Europe and Asia. It grows in temperate climates at altitudes between 190 and 1240m. It is predominantly a cool season vegetable crop. Being a cool season crop, it is sown during winter from September to January in northern plains. It is an annual or biennial crop depending upon the type and for the purpose it is grown (PCARRD, 2007).

Radish is one of the major vegetable crops in the Philippines. Due to its popularity, radish is often planted in many home gardens or raised commercially in the field. It is highly appreciated by consumers for its pungent taste. It could be eaten raw in salads, prepared as pickles or cooked with fish, meat and shrimp and other meals. Usually, people eat radish raw as a crunchy vegetable, mainly in salad, while it also appears in many European dishes. Some people prefer to drink its juice in pursuit of certain health benefits, as it has been reported to show antimicrobial activity against *Bacillus subtilis, Pseudomonas aeruginosa* and *Salmonella thyphosa*. In addition, the ethanolic and aqueous extracts have also shown antimicrobial activity against *Streptococcus mutans* and *Candida albicans*, *Sarcini alutea* and *Staphylococcus epidermidis (*Shukla et al., 2011*)*.

The roots are the most valuable and edible part of radish, although the stem and leaves have also been used for food flavoring or preservation (Beevi et al., 2009). As similar to other cruciferous vegetables, the nutritional value of radish is derived from its content of many essential minerals and vitamins, carbohydrates, high content of fiber, and low content of fat (Manchali et al., 2012). Radish has also valuable medicinal properties. It is widely used in traditional medicine in various parts of the world for treatment of different ailments and disorders affecting the respiratory, urinary, gastrointestinal systems, anemia, female, male infertilityand the skin (Aruna et al., 2012). The leaves and roots are also used as antimicrobial agents (Guti´errez and Perez, 2004). Many of the pharmacological activities of radish are attributed to the occurrence of a wide range of secondary metabolites, including alkaloids, phenolics, flavonoids (including anthocyanins), coumarins, carotenoids, antioxidant enzymes, terpenes, glucosinolates, and other compounds (Shin et al., 2015).

Radishes have different skin colors (red, purple, black, yellow, and white through pink), while its flesh is typically white. In addition, the edible root of radish varies in its flavor, size, and length throughout the world.

Fusarium wilt of radish caused by *Fusarium oxysporum* is one of the major diseases affecting the growth and yield of radish and causing annual yield losses in producing areas. Symptoms include leaves turning yellow on one side of plant; leaves fall from plant leaving a defoliated stem. Fungus can survive in soil for many years and can be spread to new areas via infected transplants, soil, insects or infested equipment. It may also be spread via infected water or by wind. The disease can be effectively managed and controlled by planting resistant radish varieties; once the pathogen has established, very little can be done to control it; spread can be prevented by sanitizing all equipment regularly; do not plant susceptible crops in previously infested soils and control of insect pest that can transmit the disease or harbor the pathogen (Thamburaj and Narenda, 2001).

The term "high-tunnel" often called a hoop house, is currently used to describe structures with a single or double (inflated) layer of polyethylene film stretched over hoops of metal or polyvinyl chloride (PVC). High-tunnels (HTs) in contrast to greenhouses, regardless of materials used, are not artificially heated or cooled, but rely on passive ventilation, which saves cost of both construction and maintenance. Tomatoes, peppers, cucumbers, melons, lettuces, summer squash and eggplants are the primary vegetable crops grown in High-tunnels with small fruit (berries) and tree fruit gaining importance.

MATERIALS AND METHOD

Study location

The experiment was conducted at the Research Laboratory of the Department of Microbiology University of Nigeria, Nsukka.

Collection of samples

Thirty leaves sample were collected at random from two environments (open field and high tunnel) in the experimental field where radish was grown, samples were thoroughly washed in sterile water. Thereafter, the infected tissues along with adjacent small unaffected areas were cut into small pieces of 2–5 mm squares and transferred by using flame-sterilized forceps to sterile Petri dishes containing 0.1% mercuric chloride solution.

Preparation and sterilization of media and glass wares

Potato Dextrose Agar (PDA) which contains 200.0g of peeled potato, 20.0g of Dextrose, 20.0g of Agar and 1000.0ml of water was prepared and sterilized for 20 minutes at 121°C for 15 minutes at 15psi in an autoclave.

Isolation of Fungi from Samples Collected

The tissue pieces were surface sterilized in this Sodium hypochlorite (1%) for 30–60 sec and washed in sterile water two or three times. The tissue pieces were aseptically transferred to Petri dishes containing a nutrient medium (Potato Dextrose Agar) supplemented with streptomycin sulfate at the rate of three pieces per plate. The plates are incubated at room temperature (25°–27°C).

Morphological Identification of fungi Isolates

Isolated fungi were identified based on colony and morphological characteristics such as colour and shape. The Morphological characteristics and appearance of the fungal isolation was confirmed and authenticated with the help of Mycological Atlas.

Microscopic Identification of Isolates

Slide Culture Technique

Slide cultures were prepared for fungal staining. For this, PDA agar blocks of the size of a cover slip were cut and placed on a sterile microscopic slide over a sterile 'V shaped" glass rod in a Petri dish. The agar block was then inoculated with the fungus on all the edges. A sterile coverslip was kept over the agar and the set up was then incubated at room temperature. After the growth of the fungus, the cover slip was carefully removed and stained with Lactophenol blue and was observed under a bright field microscope (Olympus, Model BX43) with ×10 and × 40 objectives.

Disease Incidence and Severity

Disease incidence for each environment was determined by counting the total number of plants sampled and the number of plants showing disease symptoms and calculated using the formula below:

ISSN: 2814-0508

$$\text{Disease Incidence} = \frac{\text{Total number of plants showing symptoms}}{\text{Total number of plants sampled}} \times 100$$

Disease severity was scored at intervals on a 6-point scale (Nwufo and Ihejirika, 2008):

Disease Estimation (%)	Scale	Interpretation
0	0	No infection
1- 20	1	Slight infection
21- 40	2	Moderate infection
41- 60	3	Severe infection
61- 80	4	Very Severe infection
81- 100	5	Completely infected and death

$$\text{Disease severity index} = \frac{\text{Sum of disease scores}}{\text{Total number of plant sampled} \times \text{maximum score}} \times 100$$

RESULTS AND DISCUSSION

The result obtained from the laboratory for disease isolation and identification showed *Fusarium oxysporum* causing Fusarium wilt of radish to be associated with the crop. There was high significant incidence of the disease of 57% and 70% at 2 and 3 weeks after planting in March 2018 (Figure 1). There was average severity of the disease, 34.7% and 38.3% at 2 and 3 weeks after planting, respectively (Figure 2).

In April 2018, there was significantly high incidence of 43.3% in the open field and a moderate incidence of 16.7% in the high tunnel (Figure 3), while for disease severity; the open field had a moderate severity of 26.7% and the high tunnel had a relatively low severity of 5% at 3 weeks after planting (Figure 4).

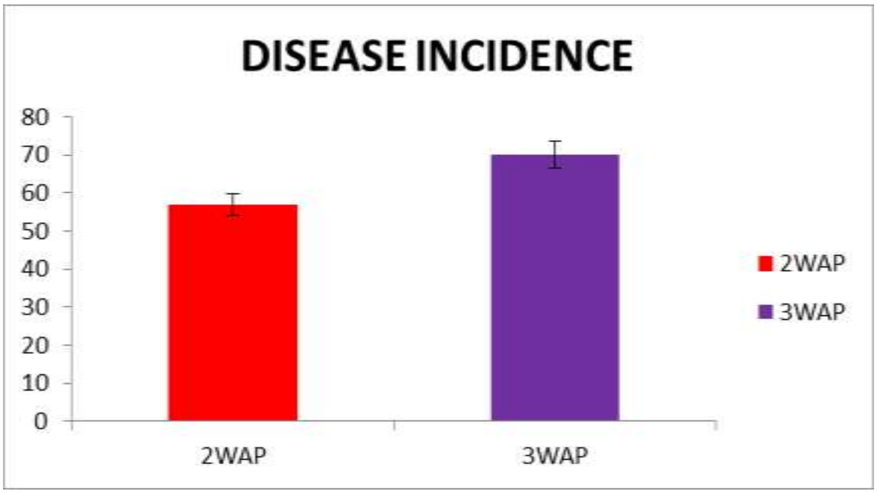

Figure 1. Disease Incidence (%) at 2 and 3 Weeks after Planting in March 2018

ISSN: 2814-0508

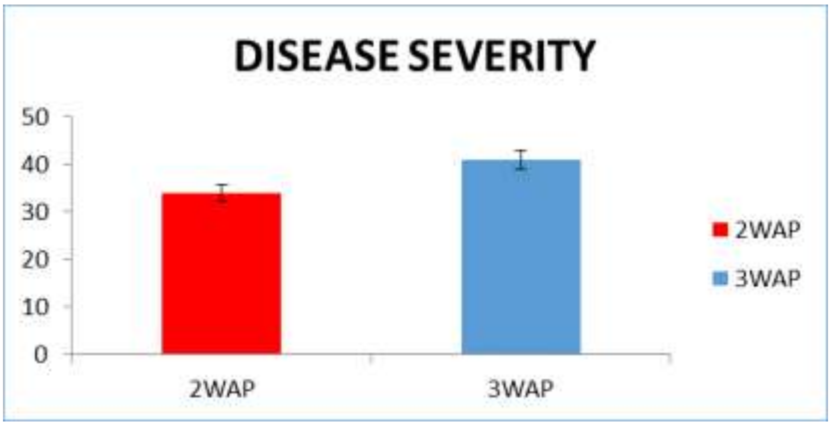

Figure 2. Disease Severity (%) at 2 and 3 Weeks after Planting in March 2018

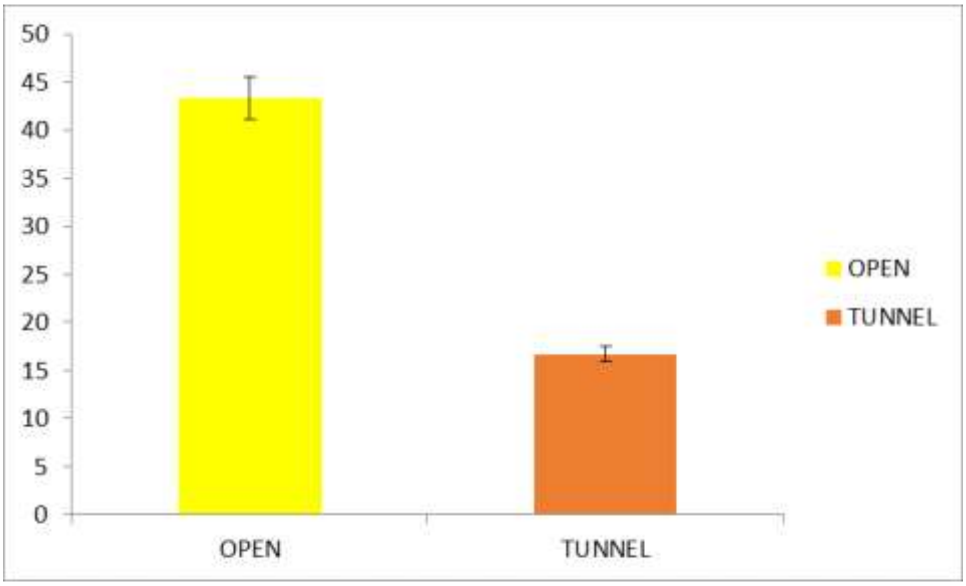

Figure 3. Disease Incidence (%) under Open and Tunnel in May 2018

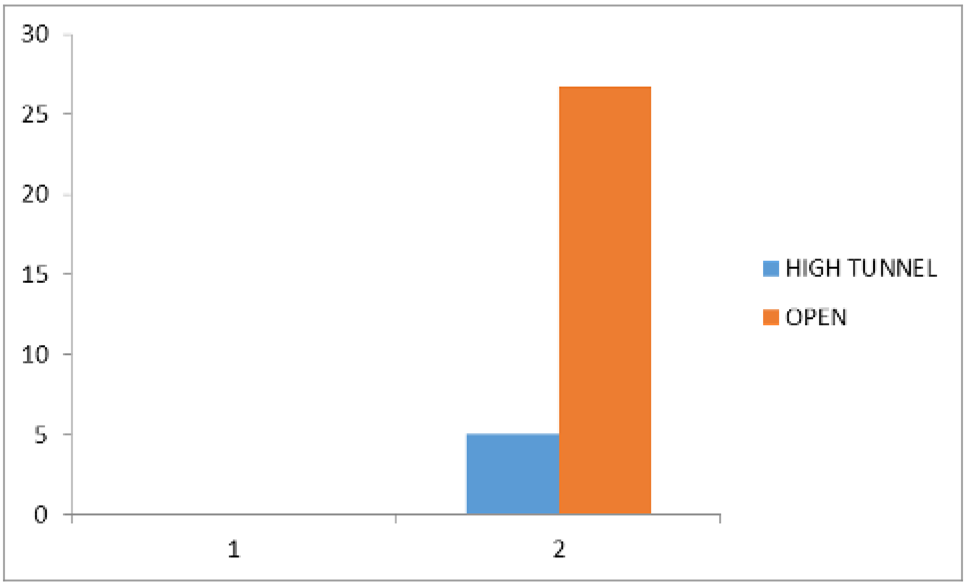

Figure 4. Disease Severity (%) under Open and Tunnel in May 2018

ISSN: 2814-0508

Results showed that the disease incidence and severity of Fusarium wilt of radish were significantly higher in the month of March than in April and May 2018, this could be attributed to the fact that both the presence and virulence of a pathogen are higher when environmental conditions are favorable as the pathogen is favoured by high temperature range of 25 to 30°C, warm moist soils and relative humidity of 70%. The relatively high temperature of 31.9°C and relative humidity of 52.0% in the month of March (Tables 2 and 3) favoured the development of the pathogen. Likewise, there was significantly higher disease incidence and severity in the open field than in the high tunnel in both months of April and May. This conforms to the report of Rhonda et al., (2017), who reported that the incidence and severity of pest and diseases are usually reduced/lower in high tunnel.

Insect pests are known to be good vectors of plant diseases. The whitefly vector *Bemisia tabaci* is known to be a vector of several host including members of the family the family Brassicaceae which radish belongs. Most of the previous and surrounding crops in both environments (Table 1) were either solanaceous plants or crops which belonged to the same host range that are infected by the Fusarium disease pathogen. Fusarium wilt is a common vascular wilt fungal disease exhibiting similar symptoms to Verticilum wilt.

Table 1. Crop history and information

Location	Farm type	Cropping pattern	Age of plant (weeks)	Previous crop	Origin of seeds	Chemical treatment	Surrounding crop
Crop science teaching and research farm University of Nigeria, Nsukka	Pot experiment	Radish as a sole crop	2-3	Green pea (field) Green pepper (tunnel)	Certified source (Netherlands via Afri-Agro Ltd in Lagos)	Use of powdered and sprayed chemicals (pesticides, herbicides and fertilizers)	Pepper, cassava, cowpea, okra, solanum, cucumber, maize (field) Green pepper, passion fruit seedlings (tunnel)

The surrounding crops harbored pest like the whitefly (*B. tabaci*) and the variegated grasshopper (*Zonecerus variegatus*) which are known to be good vectors of many bacterial, viral and fungal diseases including Fusarium wilt of radish. One of the main reasons for the success of the whitefly as a pest and vector is its extreme polyphagy and was recorded on 506 plants species belonging to at least 77 families (Basu, 1995). Alegbejo and Banwo, (2005) reported whitefly to be a vector of plants in the family Solanaceae, Cruciferae and Brassicaceae to which radish belongs. Baiyeri and Soyeye (2019) also in an unpublished article reported the incidence of Fusarium wilt on green pepper which was the neighboring crop to the radish.

Lindsey and Pelter (2003) also used Potatoes Dextrose Agar to isolate *F. oxysporum* causing fusarium wilt of radish (*F. oxysporum* f.sp. raphani), it has also been previously reported in the USA in California. Symptoms progressed from yellowing of leaf, to general wilting and die back of plant. The host range of *F. oxysporum* f.sp. raphani is limited to radish. Leeman *et al*., (1996) reported that treatment of radish seed before planting has helped in suppression of *F. oxysporum* of radish in commercial greenhouses as symptoms were localized or expanded very slowly.

ABSTRACT

This study was aimed at determination of the occurrence and prevalence rate of major viral pathogen infecting tomato in southwestern Nigeria. This was with a view to providing empirical information on the distribution of eight viruses of tomato crop in the study area. Two hundred and seventy-five (275) leaf samples from 16 major tomato producing towns spread across southwestern Nigeria were used for this study. The viruses studied were Tobacco mosaic virus (TMV), Tomato mosaic virus (ToMV), Tomato spotted wilt virus (TSWV), Tomato yellow leaf curl virus (TYLCV), Cucumber mosaic virus (CMV), Potato virus Y (PVY), Pepper veinal mottle virus (PVMV) and Tomato etch virus (TEV). Virus-specific antibodies were used for serological detection of viruses in leaf samples through enzyme linked immunosorbent assay (ELISA) techniques. The results of ELISA test revealed that 11 of the 16 areas surveyed recorded tomato viral incidence. Cucumber mosaic virus and ToMV were detected in the plant samples with percentage disease incidence of 19.27 (57/275) and 1.45% (4/275) in all eleven and two farm locations respectively. Tomato yellow leaf curl virus, TSWV, TMV, TEV, PVY and PVMV all recorded zero incidence. Samples from Ifo, Ogun State recorded the highest percentage incidence of CMV infection with 70%, followed by Ikorodu, Orile Ilugun, Iyana-Offa, Apomu, Alimosho, Sekona Ife, Eruwa, Ido, Iju-Atan and NIHORT with 66.67, 50, 32, 26.67, 20, 20, 20, 15, 13.33 and 6.67% respectively. Iwo, Araromi, Akure, Erio-Ekiti and Aramoko-Ekiti recorded no CMV disease incidence. Only Alimosho and Ikorodu recorded the presence of ToMV with percentage incidence of 20 and 13.33%, respectively. Mixed infections of CMV and ToMV were detected in Alimosho and Ikorodu. These data clearly revealed CMV as a major threat to tomato production while ToMV is an emerging virus in the area. However, PVY, TSWV, TEV, PVMV, TYLCV and TMV with zero incidence were unlikely threat to tomato production in the study area as at the time of report.

Key words: Tomato viruses, Southwestern Nigeria, Enzyme linked immunosorbent assay (ELISA).

INTRODUCTION

Tomato (*Lycopersicon esculentum*) is a crop that is planted and consumed globally providing essential nutrients, antioxidants and phytochemical of medicinal value (Causse *et al*., 2002). It is a crop cultivated in Nigeria by all ethnic groups at both commercial and subsistent scale (Olaniyi *et al*., 2010). When compared with U.S.A and Taiwan, where yields as high as approximately 180 tons per hectare has been recorded (FAO, 2013), the yield of tomato in Nigeria is very low. The average in the western part of the country being only about 5 tons per hectare and 20 tons per hectare in areas of Northern Nigeria (Olaniyi *et al*., 2010). Southwest Nigerians therefore continually depend on tomatoes from the Northern region and imported processed tomatoes from foreign countries.

Most of the tomato farms in the Southwest Nigeria are perennially plagued by prevalence of observable viral-like symptoms of mottling, mosaic, leaf curl, necrosis, leaf distortion, stunting, wilting and plant death (Kayode, 2018). These symptoms of suspected tomato virus diseases are often consistently present at every planting season and farmers are usually confused about the implicated pathogen and control measures to be adopted. The high incidence of these viral-like symptoms is a major challenge to tomato cultivation in southwestern Nigeria leading to very low crop yield and poor market value of harvested fruits (Mohammed *et al*., 2017). In view of the potential devastating impact of some plant viruses on tomato crop production and the extremely low perennial yield in Southwestern Nigeria, there is need for a thorough research designed to study the distribution and prevalence rate of eight suspected viruses infecting tomatoes in the area.

The aim of this research work was to determine the occurrence and distribution of *Tobacco mosaic virus* (TMV), *Tomato mosaic* *virus* (ToMV), *Tomato spotted wilt virus* (TSWV), *Tomato yellow leaf curl virus* (TYLCV), *Cucumber mosaic virus* (CMV), *Potato virus Y* (PVY), *Pepper veinal mottle virus* (PVMV) and *Tomato etch virus* (TEV) in samples of tomato leaves collected from selected farms in major tomato producing areas in Southwestern Nigeria. The knowledge of the occurrence and prevalence rate of major tomato-infecting viruses in Southwestern Nigeria will give more insight on the integrated pest management strategy and the best tomato cultivation practice to be adopted in the control of the predominant tomato virus(es) in the study area.

MATERIALS AND METHODS

Collection of Samples

An unbiased random sampling was conducted by collecting fresh, young expanded leaves of tomato plants at regular intervals of 10 metres along the two diagonal paths of selected farms in 16 major tomato producing areas of southwestern Nigeria. The samples included symptomatic and asymptomatic leaves. The samples were preserved in air tight McCarthney bottle pre-loaded with silica gel (Sigma Aldrich) and covered with cotton wool. Two hundred and seventy-five (275) samples were collected over the six states of Southwest Nigeria. The sample sources, farm locations, global positioning system (GPS) coordinates and number of samples collected are shown in Table 1 and Figure 1. Virus-free, apparently healthy tomato plants were raised in the screen house and two healthy leaf samples were collected for use as negative controls.

Serological indexing for CMV and TSWV in leaves samples.

ELISA antisera sets and the respective controls were obtained from the Plant virus collection centre of Leibniz-Institut Deutsche Sammlung Von Mikroorganism und Zellkulturen Braunschweig, Germany (DSMZ). Antigen coated plate enzyme-linked immunosorbent assay (ACP-ELISA) method was used for the detection of CMV, Triple Antibody Sandwich ELISA (TAS-ELISA) was used for the detection of TSWV and TYLCV while Double Antibody Sandwich ELISA (DAS-ELISA) was used for the detection of PVY, TEV, ToMV, TMV and PVMV as described by the manufacturer's manual on ACP-ELISA, TAS-ELISA and DAS-ELISA available on:
https://www.dsmz.de/fileadmin/_migrated/content_uploads/ACP-ELISA.pdf
https://www.dsmz.de/fileadmin/_migrated/content_uploads/TAS_ELISA_01.pdf ,
https://www.dsmz.de/fileadmin/_migrated/content_uploads/DAS-ELISA_01.pdf, respectively.

Assessment of results were carried out through spectrophotometric measurement by placing the plate in the ELx 800 universal multiscan ELISA microplate reader provided with 405 nm filter (Bio-Tek Instrument Inc. Winooski, VT 05404, USA) and the readings were taken after 1 hour and overnight. Samples with values exceeding twice the reading of the healthy control were considered positive.

RESULTS

Incidence and distribution of viruses infecting tomato in southwestern Nigeria

Eleven of the sixteen areas surveyed recorded viral incidence. Two of the eight viruses surveyed were detected in the plant samples. These viruses were CMV and ToMV. CMV recorded its presence in 11 locations while ToMV recorded its presence in 2 locations. The ELISA result is presented on Table 4.

Out of 275 samples collected, 57 samples tested positive to the presence of the viruses. CMV had the highest incidence with 53 positive samples (19.27 %) followed by ToMV with 4 positive samples (1.45 %). TYLCV, TSWV, TMV, TEV, PVY and PVMV all recorded zero incidence. Ifo recorded the highest percentage incidence of CMV infection with 70 %, followed by Ikorodu 66.67%, Orile Ilugun 50 %, Iyana Offa 32 %, Apomu 26.67 %, Alimosho 20 %, Sekona Ife 20 %, Eruwa 20 %, Ido Ibadan 15 %, Iju-Atan 13.33 % and NIHORT 6.67 %. Iwo, Araromi, Federal College of Agriculture Akure, Erio-Ekiti and Aramoko-Ekiti recorded no CMV disease incidence. The percentage ToMV disease incidence on the farm areas were as follows: Alimosho 20 % and Ikorodu 13.33 %. Other areas recorded zero ToMV incidence. Mixed infections were detected in two areas. These included: Alimosho and Ikorodu with CMV and ToMV infections.

DISCUSSION

The result of the prevalence study revealed the presence of CMV in 53 out of 275 (19.27 %) samples from 11 of the 16 locations visited. This was followed by ToMV with an incidence of 1.45 % (4 out of 275 samples) spread across two Lagos farm areas while the PVY, TEV, TMV, PVY, TYLCV and TSWV all recorded no incidence. These findings is an indication that PVY, TEV, TMV, PVY, TYLCV and TSWV were unlikely to be a major threat to tomato production within the study area. CMV was uncovered as a major or leading viral pathogen of tomato plants while ToMV is an emerging tomato virus in the area.

The highest prevalence rate of CMV among the viruses surveyed in locations visited could be attributed to planting of infected seeds obtained from previously harvested tomatoes which had CMV infections and/or the availability of alternative host weeds and crops serving as CMV inoculum reservoirs due to the wide host range of CMV (Palukaitis and García-Arenal, 2003; Zitter and Murphy, 2009). In fact, CMV has the reputation of having the widest host range of any known plant virus and has a worldwide distribution causing economically important diseases in a large variety of crop plants.

Another possible contributory factor leading to high CMV incidence in most farms is the observable high population of the CMV-transmitting vectors (aphid species) in and around the farms. Therefore, the absence of one or two or all of the aforementioned scenarios may have accounted for the zero incidences of PVY, TEV, TMV, PVY, TYLCV and TSWV recorded in the farms visited. These observations are noteworthy given CMV is seed borne in tomato (Park and Cha, 2002), cannot withstand drying or persist in the soil (Kansas State University, 2007); not readily transmitted by handling infected plants (Edward, 1998) and no tomato variety is resistant to any of the 8 viruses (AVRDC, 2004).

The observations also corroborate the report of Mohammad (1999) that epidemic of CMV and other cucurbit viruses which are spread by aphids in a nonpersistent manner, depend on the abundance of virus-reservoir weed and crop host plants, the abundance of insect vectors, and the proximity of virus-infected source plants to the farms. The possibility of alternative crop hosts serving as significant sources of CMV for other crops has also been reported (Zitter and Murphy, 2009). The probable CMV host plant reservoir observed within the surroundings of the tomato farms visited included pepper, amaranth green, yam, cucumber, okra, *Petunia and Solanum* species.

The emergence of ToMV in the farms visited in Lagos could be attributed to one or more factors which included: poor sanitation, unhygienic farm practices, planting of ToMV infected seeds, cultivation of tomato on lands harbouring ToMV virion particles, continuous cropping on infected land due to scarcity of arable land, presence of alternative host crops or weeds serving as inoculum, use/consumption of tobacco products on the farms, susceptibility of many vegetable crops to ToMV (Yoon *et al*., 2002) and the exchange of infected plant materials and ornamentals between neighbouring countries and Nigeria since Lagos state is an entry point into the country.

All these observations are noteworthy considering the fact that ToMV has stable viral particles and mechanically transmissible by field workers and farming instruments which enable ToMV to spread readily and make elimination difficult (Aghamohammadi *et al*., 2013). In particular, tobamoviruses can survive for long periods in crop debris and on contaminated equipment (Broadbent, 1976). ToMV may be present in the endosperm of infected seeds and up to 94 % of the seeds may contain the virus (Broadbent, 1976). ToMV has also been isolated from different ecological niches, such as soil and even water samples (Jacobi *et al*., 1992; Castello *et al*., 1995; Fillhart *et al*., 1998). Most tobamovirus species are highly virulent in the field and management strategies for their control often have not been established successfully (Strasser and Pfitzner, 2007).

CONCLUSIONS

From the results of this present study, CMV remains a major threat to tomato production while ToMV is an emerging virus in the area. However, PVY, TSWV, TEV, PVMV, TYLCV and TMV with zero incidence may be considered unlikely threats to tomato production in the study area as at the time of this report.

RECOMMENDATIONS

To control the emergence and spread of ToMV within Southwest Nigeria, appropriate integrated pest management (IPM) strategy must be adopted. Integrated pest management should start with farmer's education on proper sanitation during farm operations since man is the principal vector transmitting the virus through cultural practices and contaminated equipment. Farmers should avoid planting of tomato on ToMV endemic farm land areas because infection can be easily introduced into tomato crops through root infection from contaminated soil and in particular, *Tobamoviruses* can survive for a long period in crop debris in the soil. Crop rotation especially planting of crops outside the solanaceous plant family should be implemented in ToMV affected areas and if possible planting of vegetables should be avoided for several years since many vegetables are susceptible to infection by *Tobamoviruses*.

Considering the fact that the presence of alternative host plants and availability of transmitting aphid populations are required for CMV outbreaks and epidemic in tomatoes, farmers should eradicate all perennial weeds and wild reservoir hosts in and around fields; maintain a distance of at least 5 metres between tomato farms and surrounding weeds; plant earlier to avoid high aphid populations that occur later in the season; plant late settings as far as possible from fields used to produce early tomatoes and peppers; scout fields for the first occurrence of virus disease (where feasible, pull up and destroy infected plants after spraying them thoroughly with an insecticide to kill any insects they may be harboring); use reflective mulches to repel aphids, thereby reducing the rate of spread of aphid-borne viruses; monitor aphid populations early in the season and apply insecticide treatments when needed. Safety standards and regulations must be adopted during application of insecticides to prevent food poisoning and health hazards.

ToMV and CMV as observed in this study have been shown to present many symptom variants, making these viruses often difficult to identify from symptoms alone, the production of affordable, rapid, easy-to-use, on-the-spot ELISA diagnostic kit should be encouraged and facilitated to enhance surveillance studies, early detection and control of outbreaks and epidemics in the study area.

Other management strategies for the control of viral diseases of tomato include: planting of virus-free seeds obtained from credible sources rather than collection of seeds from previously harvested tomato fruits, raising of tomato seedlings in screen houses or nets using sterilized soil during the nursery stage and enforcement of government policy to curb the movement of infected or questionable plant materials into the country.

ABSTRACT

Plantain and Banana are two crops that remain important sources of food energy and minerals for many households in Nigeria. Like every other crop, plant viruses such as BSV cause considerable loss in yield and quality. The study was aimed to evaluate the loss in growth and yield due to natural infection by BSV and to determine the relationship between symptom expression and climatic elements. An established plantain field with high incidence of BSV was used for this experiment where 15 plants each were randomly selected and tagged based on their disease status. Data was collected monthly on growth and yield parameters and climatic information. The first appearance of symptom on infected suckers was observed at 8 months after planting (MAP). The plant height (179 cm), tallest sucker (105.5 cm) and number of suckers (4) were higher in healthy plants. The healthy plants fruited earlier at 11 MAP compare to 13 MAP for infected plant and the average yield of infected plant was significantly lower compare to the healthy plant. Also, periods of no rainfall and high temperature, infected plants showed no symptom of BSV. This study concludes that BSV delays fruiting and reduces yield of plantain cv. Agbagba by about 2 months and 34.5% respectively. In addition, BSV symptoms may not be expressed on an infected plant under non favourable conditions.

Key words: Average yield, infected plants, natural infection, rainfall, symptoms

INTRODUCTION

Banana is a major staple food, which is grown in the tropics and comprises a number of species in the genus *Musa* of the family Musaceae (Khoozani *et al.,* 2019). 'Bananas' refers to all the members of the genus *Musa*. Even though, plantains are a defined group within this genus which have the AAB genome and are characterized by the orange-yellow colour of the fruit pulp at ripeness (Soares *et al.,* 2011). Banana can be classified based on its sugar and starch content, while dessert banana produces fruits that converts almost all its starch into soluble sugar at ripening and can be eaten raw plantains produce fruits that remain starchy at maturity and need processing before consumption (Akinyemi *et al*., 2010).

Banana is susceptible to a couple of pests and diseases some of which are, *Banana bunchy top virus* (BBTV), *Banana streak virus* (BSV), *Banana bract mosaic virus* (BBrMV) and *Cucumber mosaic virus* (CMV) (Tripathi *et al.,* 2016). The *Banana streak virus* which is a plant pathogenic badnavirus of the family Caulimoviridae was first identified in West Africa in the year 1958 and now reported globally (Tripathi *et al*,. 2019). The virus can be transmitted mechanically or spread through infected suckers and by mealybug in a semi-persistent manner (Tripathi *et al*., 2016).

Despite the long-term presence of this virus in West Africa, there are paucity of information on the effect of the virus on yield of plantain, even though plantain is a major food crop in Nigeria.

MATERIALS AND METHODS

The experiment was carried out on the plantain orchard of the venture unit of the National Horticultural Research Institute (NIHORT), Ibadan during the 2019 and 2020 planting seasons. A diagnostic survey was conducted on two orchards planted with suckers from the same source and disease incidence was recorded on the two fields after initial observation showed symptoms of Banana streak virus on some of the plantain stands. The health status of the plants under natural field condition served as treatment in this experiment, symptomatic plants (showing isible symptom of BSV) and asymptomatic plants (apparently healthy plants). Thirty plantain stands of each treatment (those with BSV symptoms and those without symptoms) were tagged throughout the two orchards, the tagged plants were structured into plots and replicated five times. Data was collected on a monthly basis on parameters such as number of leaves with symptoms, number of suckers, number of symptomatic suckers, height of tallest sucker (cm), plant height (cm), total number of leaves, number of functional leaves and non-functional leaves, days to fruiting and flowering. Data collected was subjected to analysis using student t-Test.

RESULTS AND DISCUSSIONS

The symptom of *Banana streak virus* have been observed on plantain and banana as having chlorotic streaks on the banana leaves and splitting of their pseudo-stem (Dahal *et al.* 1998; Daniells *et al.* 2001). Symptom persisted on the diseases plants however the first symptom expression on new suckers was record 6 months after planting (MAP) (Figure 1). There was a systemic reduction in the number of symptomatic leaves from 5 MAP through 6 MAP and at 7 MAP there were no leaf with BSV symptom. However, symptom was observed on the new suckers at 8 MAP the number declined at 9 and 10 MAP respectively (Figure 1). The lack of symptom expression coincided with periods of no rain fall, low relative humidity and high temperature (Figure 1). The numbers of plants that expressed symptom during this harsh weather conditions were reduced compared to the number that showed symptom during the rains when the relative humidity was high and temperature is low.

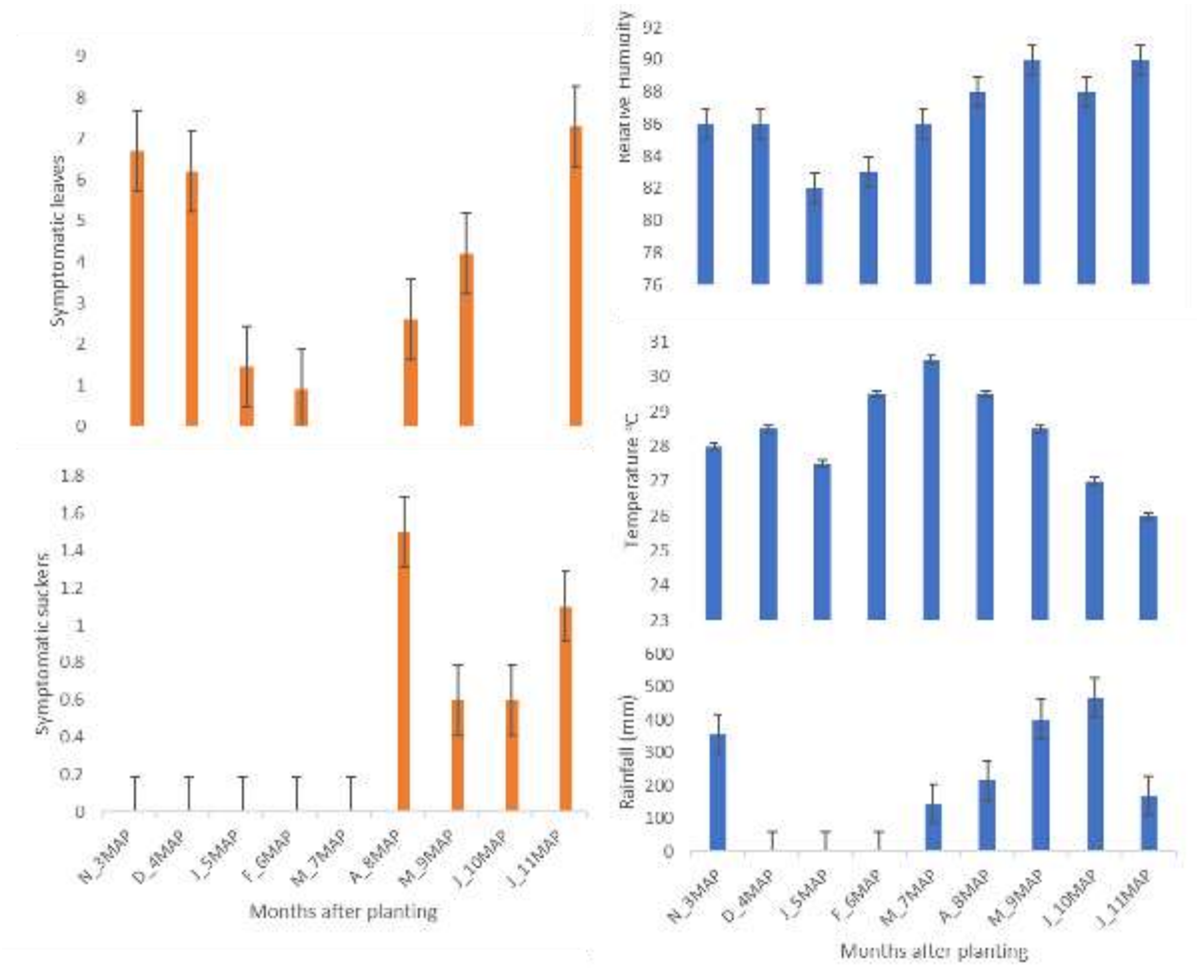

Figure 1. Number of symptomatic leaves and sucker and average weather information during the study.

Key: N_3MAP- November (3MAP), D_4MAP- December (4MAP), J_5MAP- January (5MAP), F_6MAP- February (6MAP), M_7MAP- March (7MAP), A_8MAP- April (8MAP), M_9MAP- May (9MAP), J_10MAP- June (10MAP) and J_11MAP- July (11MAP), MAP- month after planting.

The height of the mother plants, number of suckers and the tallest suckers were higher in healthy plant with 179.6 cm, 4, and 105cm respectively compared to diseases with 176cm, 3 and 87.6 cm (Figure 2). The result showed an ample variation in the growth of the healthy and symptomatic plants especially on the plant height and sucker production. Although, previous study on Cavendish variety have described the effect of the disease as small according to Daniells *et al*., 2001. The functional and non-functional leaves in the healthy and infected plants also showed a considerable variation (Figure 2). The functional and non-functional leaves in healthy plants lower at the first month after planting, however, this result showed that drought had more effects on infected plants, which led to increase in the numbers of non-functional leaves on the plants.

The fruiting in infected plants delayed by more than 2 months compared to healthy plants which started fruiting around 11 MAP (Figure 3). Yield in healthy plant was greater compared to infected plant (Figure 3). The average bunch weight recorded for healthy plants was 8kg compared to 5.25 kg average bunch weight obtained from infected plants. The findings from this study is in line with the report of Daniells et al., 2010 who suggested that the effect of BSV on yield of banana is severe in marginal climatic or soil conditions (Daniells *et al*., 2001). In conclusion, it is important to encourage an ensure the use of certified disease free seed to reduce fruiting time and increase yield which translate to increase income for the smallholder farmer that form the core of plantain production in Nigeria.

ABSTRACT

The field trial was conducted at the Teaching and Research Farm of the Faculty of Agriculture, Ahmadu Bello University (ABU), Zaria, Mokwa Station to evaluate the susceptibility of some cowpea cultivars to single and mixed virus infections. Three independent trials were conducted simultaneously, for single and mixed infections of BICMV and CPMeV. The treatments evaluated were BICMV-infected, CPMeV-infected, BICMV + CPMeV infected. The treatments were laid out in a Completely Randomized Design (CRD) with three replicates. In each trial, eight cowpea cultivars were evaluated. Seeds were sown in polythene pots of good drainage containing sterilized soil of 8 kg. Procedure of inoculation was carried out. The seedlings were watered regularly throughout their growing period. Data on disease severity were collected at 4 weeks post inoculation (WPI) while days to 50% flowering and grain/seed yield were collected at harvest. Data on severity and yield attributes were subjected to analysis of variance (ANOVA) using Statistical Analysis System. This experiment establishes that the cowpea cultivars tested are susceptible to single and double infections of BICMV + CPMeV. The study recorded a considerable stable and appreciable yield from IT07K-210-1-1 and IT97K-568-18. Therefore, IT97K-568-18 and IT07K-210-1-1 could be recommended to cowpea farmers as a guarantee against crop failure. They can also be used as sources of BICMV and CPMeV tolerant genes for breeding purposes.

Key words: Cowpea, Infections, Severity, Susceptibility, Grain yield.

INTRODUCTION

Cowpea (*Vigna unguiculata* L. Walp) is an herbaceous, warm season, annual legume crop belonging to the family Fabaceae and the sub family Faboideae. It's originated and was domesticated in Southern Africa. It was then cultivated in East and West Africa as well as Asia and today, it is grown mostly in semi-arid tropical zones across Africa, Asia, Europe and the Americas (IITA 2015). Nigeria was reported to be the largest cowpea producer which holds 3.1 million ha of land under cowpea, producing 2.5 million tonnes in 2008–2010 (Nedumaran *et al.,* 2015). The major cowpea producing States in Nigeria are Niger, Borno, Zamfara, Sokoto, Kano, Gombe and Yobe States in the northern part of the country (Idem *et al.*, 2005), since this region naturally possesses the recommended growing conditions for the crop.

Cowpea is susceptible to a complex of insect pests and diseases and they attack the crop from vegetative stage to storage (Dugje *et al.*, 2009). Virus diseases are the most damaging diseases of cowpea and represent significant proportion of losses regarding the potential value of the crop in sub-Saharan Africa. Estimated yield losses due to virus infection are between 10 and 100 % (Kareem *et al.*, 2007). *Blackeye cowpea mosaic virus* (BICMV) a important virus disease of cowpea can cause a yield loss of 13 – 87 % under field condition depending upon crop susceptibility, virus strain and the environmental conditions (Alegbejo, 2005). Similarly, *Cowpea mottle virus* (CPMeV) is highly prevalent in cowpea fields causing severe yield losses (Abdullahi *et al.,* 2020). Cowpea plants may be infected by more than one virus disease, resulting in serious economic losses in agricultural production (Alegbejo, 2005).

There are reports on mixed virus infections of cowpea occurring in Nigeria indicating that doubly infected plants will display increase in disease symptoms and in the accumulation of one or both of the viruses leading to double yield loss (Aliyu *et al*., 2012). Identifying natural sources of resistance to BICMV and CPMeV will facilitate the development and release of high yielding cowpea varieties with appreciable tolerance to the pathogens in Nigeria. This study was therefore conducted to determine the susceptibility status of selected cowpea cultivars to BICMVand CPMeV.

MATERIAL AND METHODS

The field trial was conducted at the Teaching and Research Farm of the Faculty of Agriculture, Ahmadu Bello University (ABU), Zaria, Mokwa Station (090211 N and 50135 E, 201 m above sea level) situated in the Southern Guinea Savannah Nigeria. The BICMV and CPMeV isolates used for this trial were obtained from the stock in the Virology Unit, IITA, Ibadan, Nigeria while ten cowpea cultivars (Ife Brown, IT90K-277-2, IT96D-610, IT97K-499-35, IT97K-568-18, IT97K-573-2-1, IT07K-210-1-1, IT11K-61-82, IT98K-205-M8 and IT98KD-288) were selected because they have not been endorsed against the single and mixed BICMV and CPMeV viruses.

The isolates are previously maintained on silica gels in vial bottles at room temperature. They were multiplied by propagating them in a susceptible cowpea cultivar "Ife Brown" through sap transmission before going to the field, for the purpose of being used later in the field for inoculation. Ife Brown seeds were sown in pots of 29.5 diameter and 38 cm deep containing sterilized soil. Twenty pots each placed in a wooden cage (to protect them from insect and contamination) for multiplying BICMV (10 pots) and CPMeV (10 pots) inoculum.

The sandy loam soil that was used for the study was sterilized before it was used to fill the polythene pots. Three independent trials were conducted simultaneously, for single and mixed infections of BICMV and CPMeV. The treatments evaluated were BICMV-infected (T_1), CPMeV-infected (T_2), BICMV + CPMeV infected (T_3). The treatments were laid out in a Completely Randomized Design (CRD) with three replicates. In each trial, eight cowpea cultivars were evaluated.

Seeds were sown in polythene pots of good drainage containing sterilized soil of 8 kg. Inoculation was done as earlier described during the multiplication of virus inocula. Seedlings of the first treatment were inoculated at 10 DAS with BICMV isolate, representing the single infection trial for virus A, seedlings of the second treatment were inoculated at 10 DAS with CPMeV isolate, representing the single infection trial for virus B, seedlings of the third treatment were inoculated with the isolates of Virus A (BICMV) and Virus B (CPMeV) at 21 DAS, representing type 1 double infections. The seedlings were watered regularly throughout their growing period. The control of insect pest and harvesting was carried out.

Data collected include number of pods, seed numbers and grain yield at harvest and were subjected to analysis of variance (ANOVA) using Statistical Analysis System (SAS, 2008) to verify if there are significance differences among the cultivars at $p \leq 0.05$. Significance of the difference between inoculated plants of each cultivar was determined using independent *t*-test. Where the *F*-test ratio is significant, means were separated using Least Significant Difference (LSD).

RESULTS

Severity of single and mixed infections on cowpea cultivars

Symptom expression started one week after inoculation in all the virus treatments and 85 - 100% disease incidence was attained at 4 WPI. All the inoculated plants showed symptoms in accordance to the virus types they were inoculated with and disease severity increased progressively weeks after inoculation. At 4 WPI, cowpea cultivars infected with BICMV alone and BICMV + CPMeV were of the same severity (score = 4). In the CPMeV infected plants, Ife Brown, IT90K-277-2, IT96D-610, IT97K-573-2-1, IT98K-205-M8 and IT98KD-288 were the most affected with severity score of 4 (Table 1).

The number of days to flowering of infected plants varied significantly ($p \leq 0.05$) from 56 to 62 days after sowing (DAS) in BICMV, 54 to 60 DAS in CPMeV, 59 to 67 DAS in BICMV + CPMeV (Table 1). In BICMV infected plants, IT97K-568-18 and IT07K-210-1-1 were the first to flower at 56 DAS, whereas Ife Brown was the last to flower at 62 DAS. Similarly, in CPMeV infected plants, IT97K-568-18 and IT07K-210-1-1 had early flowering (60 DAS), followed by IT97K-573-2-1 at 62 DAS. Conversely, Ife Brown and IT90K-277-2 had delayed flowering (67 DAS). In BICMV + CPMeV infected plants, IT07K-210-1-1 was the first to flower (54 DAS), followed by IT97K-568-18 and IT97K-573-2-1 (55 DAS) then IT97K-573-2-1 and IT96D-610 (57 DAS). However, IT97K-499-35 was the last to flower at 67 DAS.

In the study, the cultivars with the highest seed numbers per plant also gave the highest grain yield. Significantly highest grain yield of 218.3 kg/ha was obtained from BICMV infected IT97K-568-18 and IT07K-210-1-1 plants, in CPMeV infected plants, IT97K-568-18 and IT07K-210-1-1 had 198.2 and 219.1kg/ha respectively which are similar followed by IT98K-205-M8 which gave 161.4 kg/ha. Similarly, BICMV + CPMeV infected plants had 205.4 kg/ha whereas Ife Brown had the lowest grain yield of 101.5 kg/ha in BICMV and CPMeV while IT97K-573-2-1 resulted to a low grain yield (99.9 kg/ha) in BICMV + CPMeV infected plants (Table 1).

DISCUSSION

Cowpea is an important pulse in sub Saharan Africa but its profitable production is greatly affected resulting to poor yields. This poor yields can be attributed to attacks by pest and infection by pathogenic micro-organisms especially viruses (Taiwo *et al.,* 2007). Cowpea can be infected by one or more than one virus (related or unrelated) which results in disease symptoms and serious reductions in the growth and yields of cowpea (Kareem and Akinjogunla, 2008). The single and double virus infections in this experiment had significant and different effects on the cowpea cultivars evaluated which might be attributed to the different tolerance levels of these cultivars to the respective viruses. All the inoculated plants exhibited disease symptoms indicating their susceptibility to single and double infections of BICMV and CPMeV. This is in agreement with Abdullahi *et al*. (2020), who reported the susceptibility of cowpea to single and double infections of BICMV and CPMV. Disease severity observed in this study was based on the cowpea cultivars and the type of virus treatment. High symptom severity exhibited by BICMV infected plants and BICMV + CPMeV infected plants in the studies might be due to BICMV (potyvirus) which was used in infecting the plants alone and in combination with another virus. This is supported by Anjos *et al*. (1992) who reported that high severity can occur when the infecting or one of the infecting viruses is a member of the genus potyvirus. The growth and subsequent yield of some cultivars can be likened for both single and double infections suggesting that the response of these cultivars to double infections was not stronger than the sum of the effects caused by each of the virus in single infection. This is contrary to the opinion of Taiwo (2003) who reported that double virus infections result in greater reduction in the growth and yield of single virus infections. Most cultivars produced pods and seeds of appreciable number but hardly gave appreciable yield which is in contrast to their initial satisfactory growth. The plants inoculated with BICMV alone were the most affected as they gave the lowest grain yield generally in studies. This is in agreement with the findings of Nsa and Kareem (2015) who reported that there are cases where single virus infections had more devastating effects on the crop than double infections involving that same virus.

Table 1. Disease severity, days to 50% flowering and grain yield of cowpea cultivars infested with BICMV and CPMeV at Mokwa during the 2020 cropping season

	Disease severity score			Days to 50% flowering			Grain/seed yield (kg/ha)

Means with the same letter within the column are not significantly different ($p \leq 0.05$) SNK grouping. BICMV: *Blackeye cowpea mosaic virus*, CPMeV: *Cowpea mottle virus*, BI+ CP: *Blackeye cowpea mosaic* virus + *Cowpea mottle virus*

CONCLUSION AND RECOMMENDATIONS

This experiment established the fact that the cowpea cultivars tested are susceptible to single and double infections of BICMV + CPMeV. The study recorded a considerable stable and appreciable yield from IT97K-568-18. This experiment confirms the impact of environmental conditions on the growth and yield of virus infected plants. Cowpea cultivars IT97K-568-18 could be recommended to cowpea farmers as a guarantee against crop failure. They can also be used as sources of BICMV and CPMeV tolerant genes for

ISSN: 2814-0508

breeding purposes. Intensive biotechnological research that will result in the development of cowpea cultivars with multiple resistances to economical important viruses should be employed.

[2]Department of Crop Protections, Faculty of Agriculture, University of Ilorin Ilorin Nigeria

ABSTRACT

Single inoculation of potted grown seedling of tomato *Solanum lycopersicon* 31 cultivars commonly planted in southwestern Nigeria NHTO/0199, NHTO/0201, NHTO/0205, NHTO/0206, NHTO/0216, NHTO/0217, NHTO/0221, NHTO/0222, NHTO/0223, NHTO/0226 , NHTO/0227, NHTO/0229, NHTO/0237, NHTO/0238, NHTO/0239, NHTO/0240 , NHTO/0241, NHTO/0251 , NHTO/0253, NHTO/0259, NHTO/0263 , NHTO/0264, NHTO/033, NHTO/0340, NHTO/0342 , NHTO/0347, NHTO/0351, NHTO/0352, NHTO/0354 obtained from National horticultural research institute Jericho Ibadan genetic resourses unit (GRU) ,UC82B and Roma VF obtained from farmers fields at age 28 (2 WAT) and 4(WAT) 42days after sowing were studied in insect tight screen house temperature range of 28.5^0C-32.5^0C. Inoculated with $0.1mgml^{-1}$ of cucumber mosaic virus (CMV) at age 28 and 42 days after sowing respectively. No visible symptoms were observed in all the tested tomato plants, but acute flower abortion and significant reduction on the number of fruit and fruit weight ($P< 0.05$) at 10 WAT. The reveal that inoculation period after transplanting highly significantly ($P<0.01$) influence the tomato plant height, but significantly $P<0.05$ at 2 ,4 ,6,8 and 10 weeks after inoculation (WAI) respectively. The results indicate that cultural control strategy can be adopted in viral disease management; keeping young seedlings free of infection source for as long as possible especially when using non-resistant host cultivars so as to take advantage of disease tolerance conferred by age.

Key words: Cucumber mosaic virus (CMV), Inoculation Period

INTRODUCTION

Generally, viral infection often elicits visible symptoms such as leaf curl, mottling, shoestring, mosaic leaf pupling and distortions in plants with consequent reductions in crop growth and yield (Balogun, 2008, Oke *et al,* 2018). While reduction in plant size is the most general symptom induced by virus infection, there is probably some stunting of growth even with 'masked' or 'latent' infections, where the systemically infected plant shows no obvious sign of disease (Matthews, 1991). Cucumber mosaic virus (CMV) had been early reported to be infecting tomato in some farmers' fields in Oyo and Ogun state (Kayode *et al*, 2014, Odedara and Ayo-John, 2017). Cucumber mosaic virus has been reported to be prevalent virus affecting the quality and yield of fruity vegetable pepper and resulting into yield losses of 80% during sever epidemics (Li *et al.,*2020) it infects 1200 species in over 100 plant families and cause significant economic losses in many vegetable horticultural crops (Zitter and Murphy 2009). CMV causes systemic infection in most host plant most especially tomato, but may remain symptomless in some crops like alfaifa. Symptoms of CMV vary greatly depending on the crop infected and the age of the plant at the point of infection (Zitter and Murphy 2009). This research was carried out to ascertain the effect of inoculation period of tomato with CMV on growth and yield of 31 cultivars of tomato commonly planted in southwestern Nigeria in respect the virus control strategy.

MATERIALS AND METHODS

Twenty nine cultivars of tomatoes seeds NHTO/0199, NHTO/0201, NHTO/0205, NHTO/0206, NHTO/0216,NHTO/0217,NHTO/0221,NHTO/0222,0223,NHTO/0226,NHTO/,0227,NHTO/0229, NHTO/0237, NHTO/0238, NHTO/0239, NHTO/0240 , NHTO/0241, NHTO/0251 , NHTO/0253, NHTO/0259, NHTO/0263, NHTO/0264, NHTO/033, NHTO/0340, NHTO/0342 , NHTO/0347, NHTO/0351, NHTO/0352, NHTO/0354 commonly planted by the farmers in Southwestern Nigeria obtained from National horticultural research institute genetic resources unit (GRU) ,including UC82B and Roma VF that were obtained from farmers during survey. They were laid out in the screen house to ascertained the lines that is tolerance or resistance to the CMV viral infection. Top soil and green manure in the ratio 20:1 was thoroughly mixed and steam-heated (sterilized) for four hours and was allowed to cool for 24 hours. This soil was then poured into one-litre plastic bags. Two hundred and seventy-nine (279), one-liter plastic pots were filled with the steam-sterilized top soil and were arranged in 93 pots per replicate in screen house. Seedlings of the thirty-one tomatoes

ISSN: 2814-0508

cultivars of two weeks' old were transplanted in the sterile soil, the plants were laid as Completely randomised design (CRD) with 3 replicates Treatment combinations as shown in (Table1). Two weeks after the transplanting 31 seedlings of each replicates were inoculated with CMV virus (4weeks old), inoculation was by rubbing the two primary leaves with carborundum-dusted i.e., leaves 1 and 2 from the stem base, with 0.2 mg mL^{-1} (in phosphate buffer pH 7.2) and two weeks later another 31 sets were inoculated per replicates (6 weeks old), but the control were not inoculated. The temperature of the screen house was taken twice a week Monday and Friday at the onset of flowering. The symptoms development were observed and the agronomic data of disease severity, number of leaves plant height and the flower abortion were taken at 2 weeks intervals . The tomato fruits were harvested from each pot beginning from days of mature fruit emergence, and every four days thereafter until fruiting ceases. The fruits were weighed and counted. Cumulative weights of fruits per treatment were calculated from the periodic data. Virus concentration of the inoculated plants was determined by Das-Elisa Clark and Adams (1977). And the disease severity was assessed by visual assessment in the scale of (1-5)

Severity Rating

Virus symptom severity were scored on a scale of 1-5, based on extent of leaf damage and percentage number of leaves showing symptoms, whereby 1=1-20% (very mild); 2=21-40% (mild); 3=41-60 % (moderately severe); 4=61-80 % (severe); and 5=81-100 % very severe and no fruiting (Ssekyewa. 2006; Oke *et al*., 2017). All data collected were subjected to ANOVA and treatment means was separated using LSD at 5% probability level.

RESULTS and DISCUSSION

The results of the experiment reveals that no visible foliage symptoms were observed on the leaves, but acute flower abortion and secondary manifestation of the disease symptom after the fruit harvest i.e. the new leaves coming up from the old foliage that are almost died carried mosaic symptom.

Inoculation period and effect on the number of leaves

The inoculation period after transplanting significantly ($P<0.05$) influence the number of tomato leaves at 2 ,4 ,6,8 and 10, weeks after inoculation (WAI). However, at all the sampling period tomato plant that was not inoculated had the highest number of leaves at 10WAI while the tomato inoculated at 2 weeks after transplant had the lowest number of leaves at 2 WAI (Table 2a). The number of leaves of tomato varieties was significantly differ $P<0.05$ at 2 and 10 WAI, but highly significant ($P<0.01$) at 6 and 8 WAI. Hence, NHTO/0253 at 10 WAI had significantly higher number of leaves than UC82B which had the lowest number of leaves at 2 WAI (Table 2a). The interaction effect of inoculation periods and varieties at transplanting had no significant ($P>0.05$) effect on the number leaves obtained at 2 ,4, 6, 8 and 10 WAI respectively. Nevertheless, tomato varieties NHTO/0259 at no inoculation had the highest number of leaves at 10WAI, whlie variety NHTO /206 inoculated at 2 weeks after transplanting had the lowest number of leaves at 2 WAI (Table 2b).

Inoculation period and effect on the Plant height

The inoculation period after transplanting significantly ($P<0.01$) influence the tomato plant height at 2 ,4 ,6,8 and 10 weeks after inoculation (WAI) (Table 3a). However, at 2,4,6,8 and 10WAI, tomato that was not inoculated had the highest plant height at 10WAI while the tomato inoculated at 2 weeks old after transplanting had the lowest plant height at 2 WAI (Table 3a). The tomato cultivars differ highly significantly among themselves $P<0.01$ in the plant height at 2 4,6,8and 10 WAI, However, NHTO/0259 at 10 WAI had highly significantly highest plant height than NHTO/216 which had the lowest plant height at 2 WAI of the tomato growth period (Table 3a). The interaction effect of inoculation periods and varieties after transplanting did not significantly ($P>0.05$) influence the plant height at 2,4,6,8 and 10WAI. Nevertheless, tomato variety NHTO/0259 at 4 weeks' inoculation had the highest plant height at 10WAI, while variety NHTO /216 inoculated at 2 weeks after transplanting had the lowest number of leaves at 2 WAI (Table 3b).

Inoculation period and effect on the Disease severity.

The inoculation period after 2 weeks after transplanting significantly ($P<0.01$) influence the tomato disease severity at 6 weeks after inoculation (WAI), and also significantly ($P<0.05$) at 4 WAI. However, tomato that was inoculated 2 WAT had the highest disease severity at 6WAI (Table 4a). The tomato varieties did not significantly $P>0.05$ differ in the disease severity at 2 4,6,8 and 10 WAT. However, NHTO/0216 ,0340 and 0352 at 6 WAT had highest disease severity on tomato growth period (Table 4a). The interaction effect of inoculation periods and varieties after transplanting did not significantly (P>0.05) influence disease severity at 2,4,6,8 and 10 WAI. Nevertheless tomato variety NHTO/0259 at 4 weeks' inoculation had the highest plant height at 10WAI, while variety NHTO /216 inoculated at 2 weeks after transplanting had the lowest number of leaves at 2 WAI (Table 4b).

Inoculation period, effect on flower abortion, number of fruit harvested and the fruit weight

The inoculation period after transplanting significantly (P<0.01) influence the tomato number of flowers aborted and the number of fruits harvested (Table 5a). In other words, the inoculation period after transplanting also significantly (P<0.05) influence tomato weight harvested. However, inoculated 4 weeks after transplanting tomato had the highest flower abortion, while non inoculated tomato had lowest flower abortion (Table 5a). The non inoculated tomato had highly significant highest number of fruits harvested and fruits weight respectively. While lowest number of fruits and fruit weight was observed in tomato inoculated 2 weeks after transplanting (Table 5a). The tomato varieties differ significantly (P<0.01) among themselves in the flower abortion and number of fruits harvested but significantly (P<0.05) influence the fruit weight. However, NHTO/0253 had significantly higher flower abortion than NHTO/0223 which had the lowest at the period of tomato maturation. Tomato variety NHTO/ 0259 had highest highly significant number of fruits harvested in which the lowest was observed in NHTO/0201. The highest fruit weight was observed in NHTO/0205 and the lowest in NHTO/0221(Table 5a).

The interaction effect of inoculation periods and varieties after transplanting significantly (P<0.05) influence the flower abortion, number of fruits harvested and the fruit weight of tomato. The flower abortion was highest in NHTO/0253 at two-weeks inoculation after transplanting, the lowest flower abortion was observed in NHTO/0223 zero week after transplanting. The highest number of fruits was seen in NHTO/0259 zero weeks after inoculation while the lowest was observed in NHTO/0251 2 Weeks after inoculation. Finally, the highest fruit weight was observed in NHTO/0205 at zero inoculation and the lowest was seen in variety NHTO/0221 inoculated 2 weeks after transplanting ((Table 5b).

ABSTRACT

Chilli and sweet pepper production is constrained by weeds and viruses that easily attack plants. These spices were evaluated under different field plots to determine the impact of weed type (monocot and dicot) on virus infection and insect-vector population. These plots were categorized and maintained under four weed conditions namely: weed-free check, monocot-free, dicot-free and weedy check as treatments. Incidence and severity of virus-like symptoms were assessed bi-weekly for seven weeks after transplanting. Infection rates were consistently high under weedy check (4.4 to 4.9), intermediate under both monocot-free (3.5 to 3.8) and dicot-free (3.0 to 3.1) plots; and low under weed-free check (2.1 to 2.3). All weed types aided occurrence of aphid and white-fly which are known vectors of virus infection in pepper.

Key words: incidence, severity, alternative host, chilli, virus

INTRODUCTION

Weeds are universal constraint to all cultivated crops because they rapidly compete for growth resources (Adenubi and sanni, 2020; Arogundade *et al*., 2020). They are adaptable to adverse environmental conditions and can easily regrow from seeds or root fragments left after tillage (Bosland and Votata, 2012). Most plant viruses have weeds as alternative hosts that provide a reservoir of viruses (Arogundade *et al*., 2020). In many cases, more than one virus species attacks a pepper plant and these mixed infections eventually cause more severe disease symptoms due to synergistic interactions (Murphy and Bowen, 2006). Typical symptoms induced by virus infections include mosaic, stunting, curling and mottling of foliage or fruits (Arogundade *et al*., 2015).

Current management of virus diseases in pepper is based on the integration of several approaches such as use of protected nurseries and cultivation of disease resistant varieties (Roberts *et al*., 2004; Arogundade *et al*., 2012). Other control measures is by ensuring adequate phyto-sanitary conditions after transplanting and use of systemic insecticides to control vectors (Arogundade *et al*., 2020). The use of plastic mulches is a common practice that reduce weed pressure and virus incidence in many production fields (Bosland and Votata, 2012). Limitation of this technique is that it may not be achievable in commercial plantations because of the cost implication.

MATERIALS AND METHODS

Experimental site

This trial was carried out at the National Horticultural Research Institute (NIHORT), Ibadan, Oyo state, Nigeria (07°24.08' N and 03°50.73' E). Healthy seeds of two hot pepper cultivars (chilli and sweet) were sown in sterilized soil in nursery trays and mentained under well-protected screen-house. Watering to field capacity was three times a week for five weeks and enzyme-linked immunosorbent assay (ELISA) was used to ascertain their virus-status.

Experimental design

In the field, land was partitioned into raised beds using simple farm tools before transplanting. These beds were categorized and maintained under four weed conditions namely: weed-free check, monocot-free, dicot-free and weedy check as treatments plots. The experiment was laid out in a randomized complete block design and replicated three times within each plot.

Data collection

Biometrics was done bi-weekly from one to seven weeks after transplanting (WAT). Insects, aphids and white fly population were examined using magnifying hand lense. Then, incidence of virus infection was calculated as; percentage incidence = (number of infected plants (symptomatic plants)/total number of plants sampled) x 100. The severity of virus infection were grouped into low, intermediate and high using a standard 1.0 to 5.0 rating scale (Arogundade *et al*., 2012).

ISSN: 2814-0508

RESULTS AND DISCUSSION

The effects of monocot and dicot weed types on biometric attributes and vector population of chilli and sweet pepper are shown in Table 1. Insect population was consistently high across the treatment plots and colony of aphids and white fly aided high incidence of virus infection (Figures 1). In chilli, very high incidence of virus infection (30.2%) occured under weedy check, followed by weed-free check with 27.0% incidence. However, low incidence of virus infection occured under monocot-free and dicot-free plots with 8.9% and 8.7% incidence, respectively. These weed types serve as natural alternative hosts for insect vectors that colonize pepper plants and reduce rate of infection. In sweet pepper, high incidence of virus infection (16.4%) occurred under weedy check, followed closely by weed-free check with 16.0% incidence. These control plots were easily colonized by vectors and chilli seemed to be more prone to invading viruses. In sweet, low incidence of virus infection was consistent under monocot-free and dicot-free plots with 12.0% and 10.0% incidence, respectively.

The study revealed correlation between weed types and severity of symptoms found (Figure 2). Infections were consistently high under weedy check (4.4 to 4.9), intermediate under both monocot-free (3.5 to 3.8) and dicot-free (3.0 to 3.1) plots; and low under weed-free check (2.1 to 2.3). The low severity of virus infection found in weed-free condition was not uncommon. However, intermediate severity found in monocot-free and dicot-free conditions was closely linked to non-persistent virus transmission notably by aphids due to alternative solanaceous hosts present. The high severity found in weedy conditions was closely linked to mixed infection that occur naturally under endemic condition. Therefore, farmers should give desired attention to the manner in which they prepare their lands.

ABSTRACT

The study was initiated to investigate the high mortality of cacao cherelles reported across cocoa growing state from 2014 cropping season till date. A survey was undertaken to determine the percentage disease incidence, causal organism(s) and their percentage distributions across the affected location. Samples were collected in 3 LGAs per state across Ondo, Osun and Abia state. Routine laboratory Isolation and identification of causal organisms were done using Potato dextrose agar medium and the isolated organisms were compared with identification guide. The true statuses of the identified organisms were determined through pathogenicity test. The result shows that Ondo state has highest percentage disease incidence (94.2%) followed by Osun state (84.2%) and the least Abia with 73.4%. Lasiodiplodia species had the highest percentage occurrence (64.4%, 56.0% and 49.6%) in Ondo, Abia and Osun state respectively, while Fusarium species with 51.8%, 50.3% and 46.3% respectively followed. However, Lasiodiplodia and Fusarium spp. were implicated as the real causal organism according to pathogenicity test conducted. Further work is on-going to establish the best control or management method.

Key words: Cherelle wilt, disease incidence, causal organism(s), percentage distribution

INTRODUCTION

The cocoa tree, (*Theobroma cacao* L.), belongs to the family *Malvaceae*. It is of considerable economic importance to the producing countries, the chocolate, cocoa butter, powder and semi-finished cocoa product based companies of the western nations of Europe. The recent discovery of the health benefits of the polyphenols and flavonoids in processed cocoa products as a good antioxidant has added to the in increased demand for cocoa-based products around the world. Sequel to this development, meeting the local and international demand has become a herculean task for the producing countries of Western Africa that supply between 70-80% of processed raw bean that serves as an industrial raw material for finished cocoa products such as cocoa mass, used in making chocolate, biscuits, and confectioneries. Although these benefits, obtaining optimum yield from cacao is faced with serious challenges. Foremost among these factors that affect cocoa production is the plethora of cacao diseases, soil, and climatic conditions prevailing in the humid tropics that the perennial tree crop is grown, hinder genetic yield potential of the tree crop.

Cacao pathogens reduce the potential crop yield by an estimated 810,000 tons annually (30% of world production) and individual farm losses can approach 100%, (Guiltinan, 2007). The pathogenic organisms, soil micro flora, and fauna and plant nutrients in the tropics are variable due to the variable weather conditions of the tropics that could be hot with low relative humidity and suddenly changes becoming cloudy with accompanying heavy rainfall that results to leaching down and washing off of soil nutrients, micro flora and fauna. The rainfall also results in reduced temperature and high relative humidity of over 90%. This development affects the physiology of the cacao plant and encourages the infection and thriving of diseases of which cherelle wilt has suddenly become an important limiting factor to cacao production in Nigeria.

Matured cacao plant of fruit-bearing age produces abundant flowers of which only 0.5-5% set fruits that become young *Theobroma cacao* pods, known as cherelles. These young fruits are

ISSN: 2814-0508

commonly lost to physiological thinning known as cherelle wilt, although some evidence is now available that indicates other possible causes that include abiotic factors such as sunscald and drought and biotic such as insect pest and disease causing pathogenic organisms. Between 20-90% of cherelles (young fruit) produced by a cacao plant can be lost to cherelle wilt. Cherelle wilt was considered a physiological thinning mechanism involving vessel occlusion in the cherelle peduncle (Melnick et al. 2013). Other possible causes have also been adduced to diseases causing organisms such as *Phytophthora* species, *Moniliophythora roreri*, *Lasiodiplodia theobromae*, and *Fusarium* species among others (Thorold, 1975; Opeke, 1992; Melnick et al. 2013). Symptoms manifest when wilting cherelles stop growing, turn yellow after a week, turn blackish-brown, and mummify remaining attached to the tree (Melnick et al. 2013). Peak wilt occurs 50 days after pollination followed by a second stage occurring around 70 days after pollination (Melnick et al. 2013). Cacao insects such as adult menbracid and adult treehoppers have been shown to cause 40% cherelle wilt (Kasran et al. 1991). Other factors such as hormonal influence and deficiency of certain essential nutrient elements such as potassium, nitrogen, calcium, magnesium, copper, manganese, zinc and boron coincide with high cherelle wilting (Kasran et al. 1991).

This study, therefore, was initiated to study the pathogenic organism(s) associated with cherelle wilt disease, their percentage incidence and distribution in the cacao field in Nigeria. The findings of this study will enable the understanding of mechanism of events that occur in the wilting cacao cherelles and further update the results of previous research in the face of changing climate.

MATERIALS AND METHODS

Samples of cherelle were collected in Abia, Ondo and Osun States. Three (3) LGAs were selected per State, with 9 farms per LGA given 27 farms per State sampled. In the states covered, systematics sampling procedure was used to select three local government areas (LGAs) starting with the local government with the highest production, the one following and the third one with marginal production. Within these LGAs, using the same sampling procedure as applied for selection of LGAs, three cocoa farming communities per LGA and three cocoa farmer's farm per community were randomly selected and surveyed. These farmers' farms measured between 2- 5 hectare and the age of the farms ranged between 10 to 30 years.

Furthermore, per farm visited, 20 cocoa trees were selected. Data was obtained for the diseased and healthy cherelles per tree selected using the eyes level as height. Leaves and diseased sample cherelle were collected from the cocoa tree and put in Ziploc plastic bags and labelled properly.

Analysis of diseased cherelle samples from the states surveyed

The diseased cherelle samples obtained were taken to the plant pathology section laboratory at CRIN headquarters and pieces of lesion sections excised from the cherelle pods were then plated after normal laboratory routine on extract of Potato Dextrose agar (PDA) medium (per liter: 200g peeled and sliced *Solanum tuberosum*, 15g agar powder, 20g dextrose, 10% solution Streptomycin antibiotics) in 9cm diameter disposable plastic Petri-dishes at 3 pieces per dish for the 3 replicates dishes per cherelle pod collected. Emerging hyphae were transferred by hyphal tip on to new PDA plates to obtain pure cultures.

Morphological data were taken of relevant colony cultural characteristics (Pigmentation, colony appearance top, and bottom of plates and conidia or spore structure under x100 and x400 objectives of Olympus microscope mounted with scope 9.0 digital imagery camera to described them). Eighteen culture samples of the fungi isolates after the morphological study were sent to CABI, UK for molecular analysis.

Pathogenicity test of the fungal isolates: Pathogenicity was conducted with the fungal isolates obtained from the various states surveyed to ascertain fungal isolates that shows the same symptom(s) observed in the field.

Statistical analysis

Percentage colony count of the organisms was done using Otuonye *et al.,* (2014) formula:

$$\%\ \text{Colony count X} = \frac{\text{X number of appearance in all replicate plates x100}}{\text{Total number of all colony counts in all replicate plates}}$$

Where,

X = colony of identified microorganism in the solid media

Total number of all colony count = microorganisms (identified and unidentified)

ISSN: 2814-0508

While percentage disease incidence was calculated using Gashaw *et al.*, (2014) as follows

$$\% \text{ Disease incidence} = \frac{\text{No of infected plants units x100}}{\text{Total number of units assessed}}$$

where,

No of infected plants units = infected cherelles

Total number of units= diseased and healthy cherelles

RESULTS AND DISCUSSION

Table 1 shows percentage disease incidence obtained per state surveyed and frequency of occurrence of organisms as shown by the percentage colony count. The percentage disease incidence indicates that Ondo state has 94.2% followed by Osun with 84.2% and Abia with 73.4% (Table 1). Frequency of isolation showed that *Lasiodiplodia* spp was consistently isolated and had the highest percentage occurrence of 64.4%, 56.0% and 49.6% in Ondo, Abia and Osun state respectively, while *Fusarium* spp with 51.8, 50.3 and 46.3 respectively, followed (Table 1). Pathogenicity test conducted of the fungal isolates implicated *Lasiodiplodia* spp and *Fusarium* spp. *Lasiodiplopdia* spp.is widespread pathogen and has been associated with diseases such as wilt, fruit blight, dieback and fruit rot/pod rot in cacao (Punithalingham, 2005; Mbenoun et al. 2008; Twumasi et al. 2014; Alvindia and Gallema, 2017). *Fusarium* species have also been associated with wilt of crop plants and dieback disease of cacao (Mbenoun et al. 2008: Rosmana et al., 2013; Rachmawaty et al. 2019).

Results of molecular identification from CABI identified *Lasiodiplodia* spp, *Fusarium* spp (*Fusarium solani* species complex, *Fusarium decemcellulare*), *Aspergillus* section *nigiri*, *Colletotrichum gloeosporioides*, *Bionectriaceae*, *Trichoderma ovalisporum*. Based on the pathogenicity test and identification by CABI, it is obvious that *Fusarium solani* species complex, *Fusarium decemcellulare*, *Lasiodiplodia* spp, and *Bionectriaceaei* have been implicated elsewhere as wilt pathogen of cocoa organs and several plant hosts.

CONCLUSION

The high percentage disease incidence from the states surveyed shows that cherelle wilt could be exacerbated by pathogenic organisms aided by some soil factor, management practices and climate change.

ABSTRACT

Cocoa and cashew production are important economic activities in Nigeria, production volumes are high among other producing countries and they are leading cash crop foreign exchange earnings. These crops are threatened by many biotic constraints resulting in significant yield reduction and subsequent economic losses. Diseases are the most damaging, compromised yield in terms of quality and quantity, Phytophthora megakarya and Lasiodiplodia theobromae cause major losses in cocoa and cashew. This study focuses on characterization of established pathogens of disease conditions. Field survey was carried out targeting black pod, pod rot of cocoa in Ondo, Oyo and Cross rivers states, twig dieback, inflorescence and nut blight of cashew in Oyo state. Cocoa pods and cashew parts with typical symptom of disease conditions were collected and isolation carried out. Genera Lasiodiplodia, Botryosphaeria, Aspergillus, Fusarium, Phytophthora and Colletotricum were associated with disease conditions at varied occurrences across study areas. Morphological description of established pathogens showed presence of Botryodiplodia theobromae common to all disease conditions, P. megakarya cultured from black pod in Oyo and Cross Rivers. However, nucleotide sequences of same isolates showed diverse species identities with disease conditions. Botryosphaeria mamane was recorded in black pod (Bolorunduro, Idanre, Owena, Akure), L. pseudotheobromae in pod rot (Owena). Different strains of P. megakaya were cultured from black pod in Cross river (strain 61J5) and Oyo (strain PPG4). Lasiodiplodia theobromae was cultured from pod rot (Bolunduro, Akure, Idi-Ayunre) but were of varied strains and likewise were the strains of L. theobromae cultured from cashew twig, inflorescence and nuts in Idi-Ayunre (Oyo state). The percent identity of the cultured isolates with matched strain range from 97.47% to 100%. The genetic diversity in this study indicates knowledge gap in previous identity of Lasiodiplodia species and P. megakarya in Nigeria.

Key words: Cacao, Cashew, *Phytophthora*, *Botryosphaeria, Lasiodiplodia* Black pod, dieback

INTRODUCTION

Cocoa is an important cash crop and major source of income to many smallholder farmers in the forest region of West Africa. It is estimated that 90 % of worldwide cocoa production comes from smallholdings and most of this production occurs in areas of high biodiversity of varieties and pests' complexes. Several factors have contributed to decline and dwindling production of cocoa of which black pod disease is key factor. Black pod disease is more established in West Africa than in any other parts of the world (Adegbola, 1972). Rare report of diplodia pod rot disease of cocoa growing countries of the world and classified as an invasive species on cocoa. Cashew is very prone to wide range of pathogens which infect different parts: stems, leaves, inflorescences, apples and nuts resulting into significant and economic losses in yield and quality.

Phytophthora megakarya is the most aggressive fungal pathogen on *Theobroma cacao* L. and poses a major threat to cocoa production in West and Central Africa. It was originally identified in Nigeria in 1979 (Brasier et al., 1981). Currently, *P. megakarya* is the predominant species responsible for black pod disease of cocoa in the sub region (Opoku et al., 1997, 2000). Every stage of pod development is susceptible to infection, but immature pods are the most susceptible. The first symptom observed on cocoa pods infected by *P. megakarya* is the appearance of a small translucent spot about 2 to 3 days after infection. Under humid conditions, the spot turns brown and then darkens and spreads rapidly to cover the entire pod within 7 to 14 days. Three to five days after the appearance of the first symptom, whitish spores are produced. Pod rot symptoms due to *P. megakarya* however, are characterized by multiple lesions which spread fast and coalesce with an abundant bloom of white zoosporangia on the lesion except for about a centimetre from the advancing margin. *Phytophthora megakarya* has become the main yield-limiting factor for cocoa production in affected areas (Opoku et al., 2000), the documented host range of *P. megakarya* is limited.

Lasiodiplodia theobromae is a cosmopolitan fungus with a worldwide distribution in the tropics and subtropics with a wide host range. This pathogen has been associated with pod rot of cocoa and causes blight and dieback of cashew inflorescence and twigs in Nigeria. This study however focuses on established pathogens of pod rot and black pod of cocoa, inflorescence blight and twig dieback of cashew vis-à-vis *P. megakarya* and *Lasiodiplodia* spp. in Nigeria.

MATERIALS AND METHODS

Study location: Field survey was carried out during cocoa pod production and cashew fruiting, targeting major and established pathogens of the crops in selected study locations in Ondo, Oyo and Cross rivers state. Cocoa pods showing typical symptoms of pod rot and black pod were aseptically collected from farms in selected communities (Figure 1). Disease samples were collected in sterile Ziplock sample bags and isolation procedure carried out at the laboratory of Cocoa Research Institute of Nigeria (CRIN). The infected cocoa pods and cashew parts were aseptically excised into smaller tissues pieces of 3mm using sterile scalpel, surface-sterilized in 1% Sodium hypochlorite, inoculated on selected growth media and incubated at appropriate temperature and moisture under alternating cycles of 12hours UV light and 12hours darkness for 7days. The isolates were obtained in pure cultures. Pure cultures of isolates were transferred to Inquaba laboratory facility, Idi-Ayunre, Nigeria, for morphological character descriptions, identification and nucleotide sequences were carried out according to the methodologies of Kwon et. al., 2011.

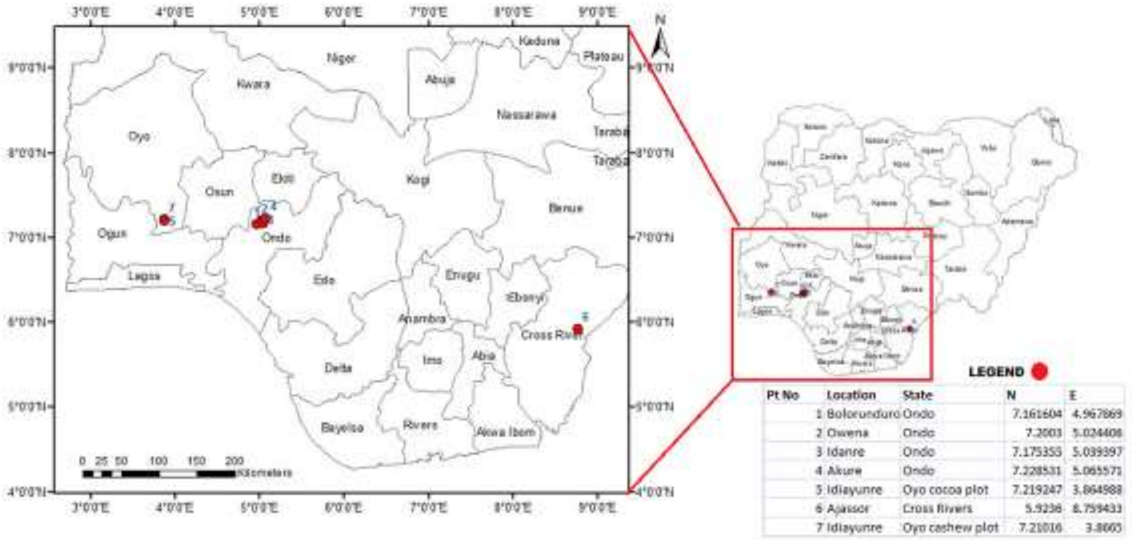

Figure 1. Map showing area of sample collection points

RESULTS AND DISCUSSION

The percent occurrence of associated organisms with pod rot and black pod of cocoa, inflorescence blight, twig dieback and nut blight of cashew varied with study locations. Total of eight genera were associated with disease conditions of cocoa and cashew.

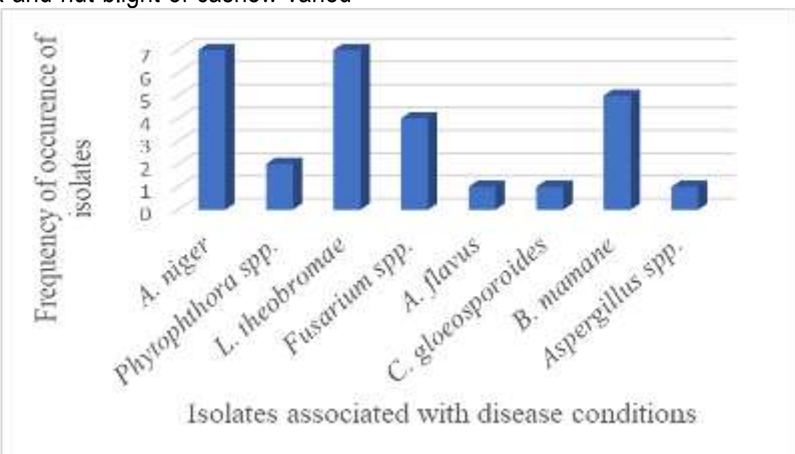

Figure 2. Occurrence of isolates with disease conditions of cocoa and cashew

ISSN: 2814-0508

Lasiodiplodia theobromae and *Aspergillus niger* recorded the highest occurrences of 25% each, *A. flavus, Colletotricum gloeosporoides* and *Aspergillus* species each recorded 3.6% occurrence in the disease conditions. *Phytophthota megakarya* had 7.1%, 14.3% and 17.8% was recorded in *Fusarium* species and *Botryosphaeria mamane* respectively (Figure 2).

Lasiodiplodia theobromae, A. niger and *Fusarium* species were cultured from pod rot of cocoa at Bolorunduro, Owena, Idanre and Akure (Ondo state). *Botryosphaeria mamane, A. flavus* and *Fusarium* were also present in Ondo state. *Botryosphaeria mamane,* which shared similar characteristic features with *L. theobromae* was common in black pod disease in all locations except Akure. Pod rot disease condition at Idanre also recorded *B. mamane. Colletotricum gloeosporoides* was also cultured from inflorescence blight of cashew (Table 1).

Colletotricum gloeosporoides has been reported as a pathogen of cashew causing a number of diseases condition on cashew inflorescence, twig, nuts and anthracnose disease in Tanzania (Zhongrun and Masawe, 2014), however this study is the first report of *C. gloeosporoides* cultured from inflorescence blight condition of cashew in Nigeria, although this pathogen have been reported associated with anthracnose disease.

Table 1. Mycoflora associated with disease conditions of cocoa and cashew

Disease condition/crop			Location
Pod rot/cocoa	Black pod/cocoa	Cashew blight/dieback	
L. theobromae	*B. mamane*		Bolorunduro

Fusarium spp.		Nut blight: *L. theobromae, A. niger*	
	P. megakarya		Ajassor

Established pathogens of pod rot and black pod of cocoa, blight and dieback of cashew were cultured, the morphological characteristics of the isolates were described in plate 1 to 4. Record of pod rot disease of cocoa was rare in Nigeria except for the incidence of the pathogen on young cocoa seedling causing dieback. The *Lasiodiplodia* pod rot disease of cocoa was first reported in Bangladesh by Shamsi et. al., 2010.

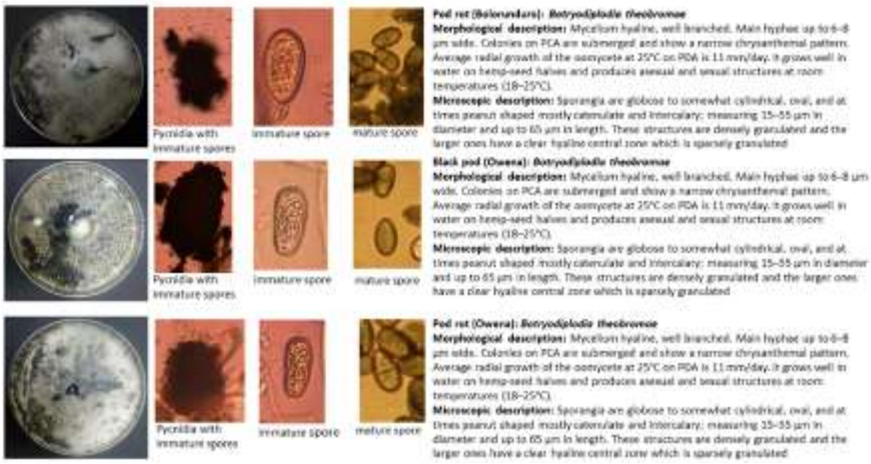

Plate 1. Morphological description and identity of pathogens on cocoa

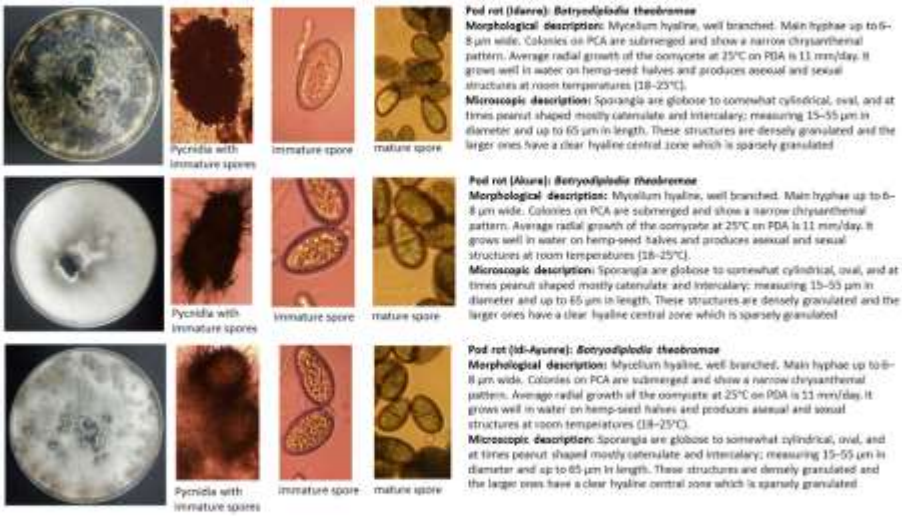

Plate 2. Morphological description and identity of pathogen on cocoa

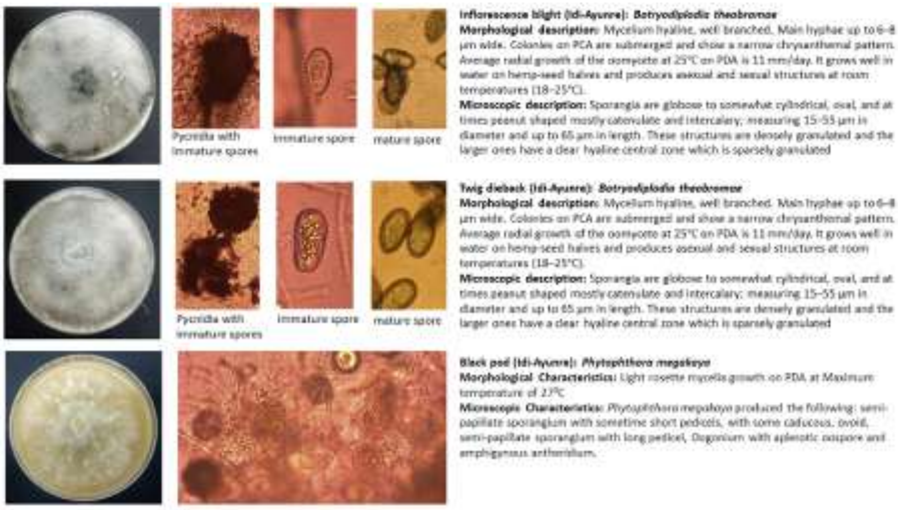

Plate 3. Morphological description and identity of pathogens on cashew and cocoa

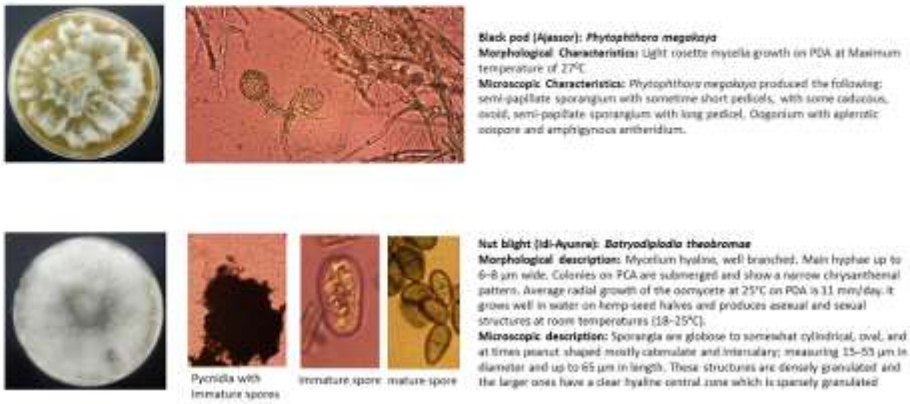

Plate 4. Morphological description and identity of pathogens on cocoa and cashew

Variations were reported in morphological characters: growth rate, sporulation, pycnidial production, colony texture and colour of *Lasiodilplodia* species associated with cashew inflorescence in Nigeria. Although all *Lasiodiplodia* isolates have one septation, but the septa size and conidial dimension also varied with source of isolates across farm locations (Adeniyi et. al., 2016). The nucleotide sequences of isolates initially reported to be *L. theobromae* through morphological descriptions showed *L. pseudotheobromae* (CUZF1QNA), *L. pseudotheobromae* (PLM-590A), *Botryosphaeria rhodina* (UCD1028BC), *L. theobromae* (670004), and *L. theobromae* (isolate 8) from cashew inflorescence blight condition (Adeniyi and Asogwa, In-press) and occurrence of *Cophinforma atrovirens* on inflorescence blight of cashew was first reported in Nigeria by Adeniyi et. al., (2020).

In this study, *L. theobromae* also showed varied strains in pod rot of cocoa: *L theobromae* (ELS4), cultured at Bolorunduro, *L. pseudotheobromae* (UY1356) at Owena, *B. mamane* (CBS117444) at Idanre and *L. theobromae* (BT02) isolated at Akure. The *L. theobromae* (zm13581) was cultured from black pod disease and pod rot of cocoa at Idi-Ayunre, Oyo state while *Aspergillus* species and *Fusarium* were associated with pod rot at Idi-Ayunre. Varied strains of *P. megakarya* were cultured from black pod at Idi-Ayunre (Oyo state) and Ajassor (Crossrivers state), PPG4 and 61J5 strains respectively. The *L. theobromae* were also occurred in varied strains in cashew disease conditions; GUCC9240, SKJM1103 and gi from inflorescence blight, twig dieback and nut blight respectively at Idi-Ayunre, Oyo state. *Aspergillus niger* was commonly associated *Lasiodiplodia* species on cashew (Table 2).

Table 2. Nucleotide sequences of pathogenic isolates in cocoa and cashew

Target crop	Matched organism			Location
Cocoa	Pod rot	Black pod		
	L. theobromae (ELS4)	*B. mamane* (CBS 117444)		Bolorunduro

ABSTRACT

The diversity and impact of insect species associated with roselle (Hibiscus sabdariffa L.), a food, fibre and pharmaceutical resource plant, varies from one location to another. Insect infestation on the crop at the vegetative growth stage was monitored at Makurdi, Benue State in 1m x 1m grid in each of 24 field plots planted to the green and the red types of roselle. The numbers of insects collected from both types were compared using Student's t test. Thirty-five species of insects in 19 Families and 6 Orders were collected from seedling emergence [1 week after planting (WAP)] to late vegetative stage (9 WAP). Majority of the insects were categorized as pests, five were predators, one a parasitoid and few incidentals. Monolepta thomsoni Allard was the most abundant (36.7-39.8 % of total collection) followed by Nisotra sjsostedti Jacobi (25.0 %); their infestation straddled seedling emergence to late vegetative stage. The least abundant species were Aulacophora africana Weis., Cylas puncticollis Boh., and Cardiophorus hoploderus (0.02 % each). Of natural enemies, Exochomus flavipes Thunb. was the most abundant (1.08 % of total collection). Number of species and population density increased phenomenally from 7 WAP and peaked at 9 WAP with concomitant severe damage to foliage. The mean number of insects collected on the green roselle (71.5 ± 32.8) was significantly (tα = 0.05) higher than the number collected on the red roselle (65.9 ± 30.8).

Key words: *Hibiscus sabdariffa,* roselle, insects, vegetative growth stage

INTRODUCTION

Roselle (*Hibiscus sabdariffasabdariffa* L.) in the family Malvaceae is an important vegetable crop in tropical and sub-tropical regions of the world (Ahmed *et al*., 2012). In Africa, the major producing countries include Republic of Benin, Sudan, Cote d' Ivoire, Ghana, Niger, Burkina Faso, and Nigeria (Oyewole and Mera, 2010). *H. sabdariffa* var. *sabdariffa* is grown for its fleshy, shiny-red calyx, while *H. sabdariffa* var. *altissima* is grown for its fibre.

The domestic and industrial uses of Roselle include: making herbal tea and beverage from calyx and bracts, preparation of soup/sauce using calyx and bracts, consumption of leaves and stalks as green vegetable/salad, trado-medicinal usage for treatment of diverse ailments and usage in paper industry (Mahadeva and Shivali, 2009). The objective of the study is to determine species composition of insects associated with Roselle [*Hibiscus sabdariffa* L.] at the vegetative growth stage in Makurdi, Benue State Nigeria.

MATERIALS AND METHOD

Experimental Location and Source of Seed: The experiment was conducted at the College of Agronomy Experimental Field, University of Agriculture, Makurdi (Latitude 07^0 45 - 07^0 50 N, Longitude 08^0 45 - 08^0 50 E, elevation 98m above sea level). Seeds of green and red varieties of Roselle were sourced from the market in Makurdi, Benue State.

Field Plot Layout and Data Collection

Twelve plots were sown to green and red types of Roselle, each plot measured 5 m x 5 m. On rows 2 and 4 of each plot, 1 m^2 area was selected at random to document insect species infesting the crop and the number of individuals of each species observed

Data Analysis

The relative abundance (Ar) was calculated according to the method of Zaime and Gautier (1989):$Ar(\%) = \frac{Ni}{N} \times 100$

where Ni is the number of individuals of a given species and N =the total number of individuals of all species.

RESULTS AND DISCUSSION

The total count of insects on the two Roselle varieties amounted to 35 different species belonging to 6 insect Orders: Coleoptera (19 species), Hemiptera (7 species) Homoptera (2 species), Hymenoptera (2 specie), Orthoptera (4 species) and 19 Families were collected from seedling emergence (1WAP) to late vegetative stages (9 WAP). The composition of insect pests and natural enemies on Roselle are given in Table 1 and Fig. 1. The number of insect species (35) collected at the vegetative stage of growth of Roselle at Makurdi approximates the total number (36) collected by Daramola (1984) in southwestern Nigeria throughout the crop's growth. Members of three Families and two Orders not reported from southwestern Nigeria were collected.In both studies, coleopterous insects predominated and the numbers of predatory species were similar (6 and 5 in southwestern Nigeria and Makurdi, respectively The leaf eating beetles, *Monolepta thomsoni* Allard, *Nisotra sjostedti* Jacoby were the dominant insect species (they appear in large number at the same time) at the seedling and early vegetative stages of the crop, they feed on the leaves and cause small round holes. *Monolepta thomsoni* Allard (36.7-39.8 % of total collection), recorded the highest relative abundance followed by *Nisotra sjsostedti* (25.0 %) Jacoby.*N. sjostedti* are known insect pest of Kenaf (*Hibiscus cannabinus* L.), Okra (*Abelmoschus esculentus* (L.) Moench) and other malveceous plants (Echezona *et al*., 2010, Amujoyegbe *et al*., 2016). Flea beetles [*Nisotra sjostedti*; *Monolepta thompsoni*], grasshoppers [*Aiolopus thalssimus*; *Acrida bicolor*], and whiteflies [*Bemisia tabaci*; *Empoasca* sp.] were early colonizers of the crop and they persisted through to late vegetative stage (Plate 1-4). Other species include *Asbecesta cyanipennis* Har. (7.5%), *Acrida bicolor* Thunb *Acrida bicolor* Thunb (2%), *Bemisia tabaci. Cennadius* (2.6%). The least abundant species were *Aulacophora africana* Weis., *Cylas puncticollis* Boh., and *Cardiophorus hoploderus* Can. having relative abundance of 0.04% each

In Fig. 1, The first of the natural enemies was sighted from the 3rd week post-planting having been preceded by 2 weeks by insect pests of the crop. Five natural enemies were recorded during the study, *Exochomus flavipes* Thunb. was the most abundant (1.08 % of total collection).

The mean number of insects collected on the green roselle (71.5 ± 32.8) was significantly (tα = 0.05) higher than the number collected on the red roselle (65.9 ± 30.8). The number of insect species and abundance of each increased with the crop's growth and increased with opportunity for finding mates culminating in severe foliage damage at the late vegetative stage [Plates 1-4]. Insects tended to prefer the green Roselle but the degree of foliage damage did not give indication of the resistance of the red Roselle to insect attack.

CONCLUSION

The current study has shown that there are various foliage insects pest attacking roselle plant. The dominant insect pests recovered during the study include: *Monolepta thomsoni*; *Nisotra sjostedti*; *Aiolopus thalassinus* and *Acrida bicolor*. Natural enemies were also encountered during the study with *Exochomus flavipes* being the most predominant species.

ABSTRACT

A sudden logging of branches and stems of bitter leaf (Vernonia amygdalina) was observed in the Orchard of National Horticultural Research Institute, Ibadan as a result of continuous boring and tunneling by neonate larva Lixus camerunus during the raining season of year 2020. The first observation was on the 4th of May, 2020 with about 58.87 newly hatched weevil found on 10 sampled shrubs, the observation period lasted for eight weeks and ended on the 22nd of June, 2020, measurement of stem size, number of branches, length of branches, stem above the ground and height of the plant was carried out. Larva population, length of tunneling by larva, number of lodged branches and quantity of marketable yield was determined. The study shows positive relationship between stem size of Vernonia amygdalina and the length of tunneling by neonate larva of the weevil. Ten sucking and piercing insects "Thrips, Aphids, Emposca spp, whiteflies. Lady beetles, Black ants, Spheaorocoris annulus, Fabricius spp, Polyclaeis spp and Xanthochelus vulneratus" were found on each of the tagged plant. Planting space modification, early harvesting and early detection of insect pests are recommended to be integrated into the pest management package for the control of Lixus camerunus

Key words: *Lixus camerunus, Vernonia amygdalina,* tunneling, larva

INTRODUCTION

Vernonia amygdalina, is a perennial shrub from the Asteraceae family commonly called 'Bitter Leaf' because of it bitter taste. Bitter leaf also has a lot of other local names in different languages of the different regions of the world, such as Ewuro, Onugbu, Oriwo, Etidot and Ityuna in Nigeria and Awonwono in Ghana (Farombi and Owoeye, 2011). Bitter leaf is one of the Africa underutilized Crops and of economic value. Vernonia has close to 1000 species in its family (Keeley and Jones, 1979). The genus Vernonia gets its name after an English botanist, William Vernon who identified the plant in Maryland, in the late 1600s before his death in 1711 (Quattrocchi, 1999). This herb has been domesticated in many parts of West Africa, but grows freely in tropical Africa (Igile *et al*., 1994), it is also well distributed in Asia (Oseni and Babatunde, 2016). Nigerians are more aware about its benefit and have been utilizing this plant to its maximum usage as it has many health benefits compared to other regions. Despite the great value placed on bitter leaf, it is faced with insect pest infestation which has greatly reduced it production. Most of the pests that usually attack this shrub are Coleoptera curculionidae, weevil *Lixus camerunus* and *Zonocerus variegates* which utilize it as a source of protein (Eluwa, 1979). Ucheck Fomum, 2004 have also reported that thrips, aphids, ants, white flies, *Empoasa spp*., *Sphearocoris annulus* and *Fabricius spp* also attack *V. amygdalina.* The damage to stem and other parts of the plant has greatly contributed to death of many homestead bitter leaf plants, which calls for more attention to the control of *Lixus camerunus.* The objective of this research work is to determine population threshold of weevil *Lixus camerunus* as it affect the productivity of *V. amygdalina* in Ibadan.

MATERIALS AND METHODS

Establishment of the *V. amygdalina* orchard:

On the 7th of June, 2018 some stems of *V. amygdalina* accession was collected from an homestead garden in a nearby village not far from National Horticultural Research Institute, Ibadan (Latitude N7.40479 E7^{0} 24^{l} 17.2404'' and Longitude N3.85183 E3^{0} 51' 6.59916''), located in the rainforest region of western Nigeria, the accession was coded as Oy-NHRT-18, the coding was done for easy identification, Some portion of land measuring 1200m^2 at National Horticultural Research Institute, Ibadan was marked out and cleared manually, it was manually harrowed and bedded into plots of 2m^2. Blanket application of cured poultry manure was applied during land preparation and left for 3 weeks before planting the

ISSN: 2814-0508

bitter leaf stems measuring 50cm. Four stems were planted per plot and replicated eight times All other agronomic practices were carried out as at when required. The stems have since growned over the years into shrub with varying heights, branches and leaf canopy which has predisposes it to arrays of insect pest

Infestation by insects:

Observations of the infestation by *Lixus camerunus* was noticed on the bitter leaf shrub located in the orchard measuring 1200m^2 at National Horticultural Research Institute, Ibadan, Nigeria (3º5 E, 7º3 N, and 168 m above sea level). The first adult weevil was noticed boring stem of *Vernonia amygdalina* on the 4th of May, 2020.

Counting of larvae / branch:

This was achieved through destructive sampling; sampling for weevils commenced on the 4th of May, 2020 and continued every week till eight different sample periods were achieved. six branches with tunnel holes was tagged for assessment. A sterilized budding knife was used to cut off the tagged branches with bore holes and taken to the entomology laboratory to check for presence of eggs, larvae, adult weevil, and length of tunneling per harvested branch. Some other data collected are number of bore holes per plant. Larvae and eggs were carefully removed for counting using a camel hair brush.

Physical parameters data taken on the 10 shrubs:

The diameter of bitter leaf shrub stem immediately above ground and height of shrub were measured. Number of branches per shrub was counted. Six branches per tree were tagged and their length and diameter (where it is joined to the main stem) were measured.

Statistical analysis

Descriptive statistics including range (maximum and minimum) and standard deviation of the trees quantitative traits were calculated. Data on number of eggs, larvae and adult weevils / branch were subjected to analysis of variance, significantly different treatment means were separated using Student Newman Keuls (SNK) (SAS, 2009) (P=0.05) and the Least significant difference (LSD) with GENSTAT software (Genstat, 2006) (P=0.05).

RESULTS AND DISCUSSION

On 4th May, 2020, some few numbers of adult *Lixus camerunus* were observed feeding on stems and branches of ten *V. amygdalina* shrubs which ranged between 1.17m - 4.10m height, 1.10cm - 8.35cm stem girth, 11-32 branches and height of stem above ground level ranging between 0.06m - 0.88m (Table 1) in the orchard of the National Horticultural Research Institute, Ibadan, Nigeria. On 4th May when the 1st sample was taken a mean of 12.30 larvae was found inside the tunnels of the branches which ranged between 0.78m - 2.10m (Table 1) were observed on branches length which ranged between 0.78m - 2.10m (Table 1). Subsequently, the number of larvae continued to reduce weekly until the population increased on 25th May, 2020, forth weeks after the first observation with a mean numbers of 19.72 larvae per branch (Table 2). The highest mean population was recorded on 8th June, 2020 with a larval population of 31.30 young weevil tunneling on different branches and stems of the shrub resulting into logging and death of the plant. On the 22nd of June, there was a drastic reduction in population of the young weevils. (4.02 larvae/ branch). A peak population of 104.60 larvae was estimated on the 10 shrubs on an area of 1200m^2. Some of these insect pests "Thrips, Aphids, *Emposca spp*, whiteflies. Lady beetles, Black ants, *Sphearocoris annulus*, *Fabricius spp*, *Polyclaeis spp* and *Xanthochelus vulneratus* were also found sucking and defoliating leaves. Some were observed to be aborting fresh flowers which is in agreement with the findings of Banjo *et al.* 2006. However, in the orchard many species of bird and lizard were observed preying on the larvae. The peak larval population was noticed on the 5th of June 2020, with peak mean population of 31.30 larvae on a branch. Table 2 shows that the higher the population of newly emerged weevils the longer the tunneling inside the branches which results into more damaged stems and eventual production of unmarketable leaves (Plates 1-3).

Plate 2. Transverse section of tunneled branch

ISSN: 2814-0508

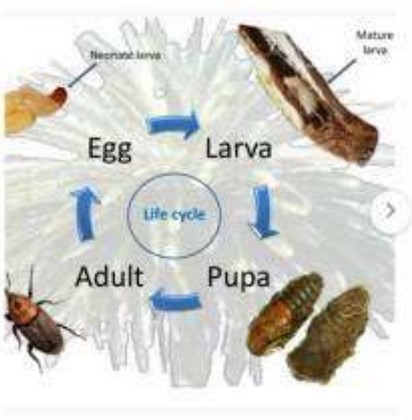

Plate 3. Lifecycle of *Lixus camerunus*

The sudden lodging of stems and branches was noticed on some of the bitter leaf shrubs in the orchards of National Horticultural Research Institute, Ibadan, Nigeria. The study showed array of insect at different population level of different insects found feeding on both leaves and stems of the bitter leaf shrub. Some of the identified insect pests are Thrips, Aphids, *Emposca spp*, whiteflies, Lady beetles, Black ants, *Sphearocoris annulus*, *Fabricius spp*, *Polyclaeis spp* and *Xanthochelus vulneratus*, with whitefly been the most abundant (134) and *Fabricius spp* (11) been the lowest. The newly emerged *Lixus camerunus* was found to be responsible for the lodging and drying up of leaves on the branches, at the onset tunneling direction by larvae was upwards, but on the death of shoots, larvae reversed direction and moved downwards along old tunnels. However, newly-emerged larvae on leaf petioles, tunneled downwards to the main branch, before pursuing an upward course. There was a significant relationship between length of tunnel and stem diameter, the bigger the stem, the longer the length of tunneling, the stem with the biggest size 8.33 cm recorded the longest tunneling 12.4 cm while the plant with the smallest stem size 1.10 cm recorded the shortest tunneling 1.55 cm, and this is in agreement with the findings of Okiwelu, 2011. These same economic insect pests have been reported by Banjo *et al* 2006 as it was found engraving holes and laying eggs inside the stems of *V. amygdalina*. The following parameters were observed on ten selected tagged bitter leaf plant, Stem height above ground, Height of shrub, Number of branches, Diameter of branches, Length of branches and Stem girth. The observation started on the 4th of May, 2020 and ended on the 22nd of June, 2020. Height above ground (trunk) ranged between 0.06-0.88 meters, height of individual plant ranged between 1.17 - 4.10 meters, number of branches ranged between 11 – 32, diameter of branches ranged between 0.95 – 4.95 cm, length of branches ranged between 0.78 – 2.10 meters and stem girth between 1.10 – 8.35 cm. There were differences in the numbers of newly emerged young adults found tunneling within the stems at different sampling period; this could be attributed to weather parameters (rainfall and temperature) during the period under observation.

CONCLUSION

This study reveals that the vegetable *V. amygdalina* cultivation in Ibadan is faced with many challenges, with insect pests playing major role in destroying many orchards. Larva stage of *Lixus camerunus* has the ability to completely destroy a whole orchard during the early season of the year. The boring activity tends to cut off nutrient supply to other parts of the plant. It is, therefore, necessary to develop an Integrated Pest Management package to deter egg lying by adult weevil. Further study will be necessary to determine the best period of control to increase marketable yield. The study also shows positive relationship between stem size and length of tunneling resulting into quantifiable losses of marketable leaves. There is need to look into modification of planting distances, frequency of harvesting and early detection of insect pests to achieve profitable *V. amygdalina* farming.

ABSTRACT

A continuous boring and tunneling by neonate larva of Lixus camerunus during the raining season of year 2020 was observed on Vernonia amygdalina causing significant level of damage. This situation prompted interest in surveying 100 homestead gardens and few orchards within Ido Local Government to access the level of insect damage and monetary losses. Demographic information such as, marital status, educational level, household size and farm size were examined while market information such as output Price, loss caused by Lixus camerunus, and expected yield in the absent of the pest. Majority of the respondents are the male gender within their early age of 40 years, 77% of the despondence are married, and losses were categorized into severe, medium and low loss. The percentage loss caused by Lixus camerunus on bitter leaf on the sampled household was estimated to be 63% herbage yield loss which places the insect into the category of a major insect pests and calls for urgent action towards controlling it.

Key words: Yield loss, *Lixus camerunus, Vernonia amygdalina,* Ido

INTRODUCTION

Vernonia amygdalina Del can be used for many purposes and it has rapid regenerating soft wooded shrub of 2 to 10 m tall with petiolate leaves of around 6 mm in diameter. This plant hasdifferent names by different ethnics around the world. It belongs to specie under the genus Vernonia Schreb (Family: Compositae; Order: Asterales; S/C: Asteridae; Classes: Dicotyledons) which contains about 1000 species. More than 500 of these Vernonia plants are distributed in Africa and Asia, approximately 300 in Mexico, Central and South America and around 16 can be found in the United States. Austin (2000) has found that even taxonomy of V. amygdalina from different geographical area (Ethiopia and Cameroon) could be different. One of the proposed solutions is through classification of the active chemical compounds, isolated from each species (Mabry et al., 1975). V. amygdalina produces a variety of flavonoids and bitter sesquiterpene lactones which contribute to the bioactivities of this plant (Nangendo et al., 2002; Favi et al., 2008).

Africa has arguably one of the richest phytodiversities in the world. Africa's forests geographically span approximately 216,634,000 per ha (Farombi, 2003). More than 50% of all modern clinical drugs are of plant origin (Suffness and Douros, 1982). Plant products therefore play an important role in drug development programs of the pharmaceutical industry (Baker et al., 1995; Cordell, 1995). Furthermore, the consumption of plant materials is believed to contribute immensely to the improvement of the health of man and his plants and animals. Yedjou et al. (2008) estimated that 80% of the population of Africa depends on medicinal plants to satisfy their health care requirements. Knowing the nutritional, medicinal and economic value of vegetables found in Africa could add value to their cultivation, one of the major factor that affect the productivity of *Vernonia amygdalina.* Most of the pests that usually attack this shrub are Coleoptera curculionidae, weevil *Lixus camerunus* and *Zonocerus variegates* which utilize it as a source of protein (Eluwa, 1979). Ucheck Fomum, 2004 have also reported that thrips, aphids, ants, white flies, *Empoasa spp*., *Sphearocoris annulus* and *Fabricius spp* also attack *V. amygdalina.* The damage to stem and other parts of the plant has greatly contributed to economic loss to bitter leaf plants, which calls for more attention to the control of *Lixus camerunus.* The objective of this research work is to determine economic loss caused by weevil *Lixus camerunus* as it affect the productivity of *V. amygdalina* in Ibadan.

MATERIALS AND METHODS

Study area

Ido Local Government is one of the Local Government Areas in Oyo state, Nigeria. It has its headquarter in Ido town. It has latitude: 7.50678 longitudes: 3.71186 altitudes. On the account of extensive fertile soil, which is suitable for agriculture, the basic occupation of the people is farming. There are large hectares of grassland which are suitable for animal rearing, vast forest reserves and rivers. People in the area grow varieties of cash crops such as cocoa, kola nut, palm oil, timber and food crops such as tomato, amaranth, maize and rice.

Source and type of data

Primary data was collected with the aid of a well-structured questionnaire which was administered to the *V. amygdalina* farming household head in particular to collect the social economic characteristics, and other relevant information.

Sampling procedure

A multistage sampling procedure was used in selecting the respondents for this study. The first stage involved a purposive selection of 100 *V. amygdalina* farming household head in the LGA. The primary data that was collected were demographic information, marital status, educational level, household size, farm size, market information like prices of output, loss caused by *Lixus camerunus*, and expected yield in the absent of the pest infestation.

Analytical tools

Descriptive statistics

Descriptive statistics such as frequencies and means were used to profile socio economic, credit status and production characteristics of the tomato farmers in the study area.

Economic loss caused by *Lixus camerunus* on bitter leaf

Percentage economic loss is estimated by finding the difference between the expected income and actual income on bitter leaf divided by actual income multiply by 100.

$$\%\ LOSS = \frac{\Delta income}{actual\ income}\ X\ 100$$

RESULTS AND DISCUSSION

The result shows that majority of the respondents are of male gender, mean age of the respondents is 40 years, majority of the respondents of about 77% are married, mean age household size of the respondents is 6 people and years of education of the respondents is 5 years (Table 1).

Percentage loss

The percentage loss is categorized into three, those that have severe, medium and low loss (Fig. 1).

The percentage loss caused by *Lixus camerunus* on bitterleaf is estimated to be 63%. This is a great loss and this need urgent attention to increase the profitability of the vegetable.

$$\%\ loss = \frac{\Delta income}{actual\ income}\ X\ 100$$

$\%\ loss = \frac{35720}{56632}\ X\ 100$ % loss = 63.07%

ABSTRACT

The Mango Mealybug, Rastrococcus invadens Williams (Homoptera: Pseudococcidae), a native of India, is a serious exotic pest of horticultural crops, especially mango. For its control, its exotic parasitoid, Gyranusoidea tebygi, was imported from India, reared, and released, successfully established nation-wide However, the resurgence of the mango mealybug was noticed in Abeokuta a few years ago, the reason for which is not yet clear. This study therefore, investigated the distribution, host range and natural enemy complex of the insect in Abeokuta metropolis. The reconnaissance surveys revealed the presence of the pest in Abeokuta metropolis on no other host plant but mango trees only. The surveys also confirmed the establishment of Gyranusoidea tebygi and the presence of the local parasitoid, Anagyrus aurantifomis, which contributed meaningfully to primary parasitism, as well as Leopardina sp. and Chartocerus sp. which are hyperparasitoids which both contributed 41.6% to secondary parasitism, were also recorded. The socio-economic implications of the infestation were also discussed.

Key words: *Rastrococcus invadens,* mango mealybug, mango, Abeokuta, *Gyranusoidea tebygi, Anagyrus aurantifomis*

INTRODUCTION

Mango, *Mangifera indica* (Anacardiaceae), is one of the most profitable crops in tropical and subtropical regions of the world and is renowned for its excellent flavour, attractive fragrance, and high nutritional value (Shah *et al*., 2010). In Abeokuta, mango trees are found along major roads, car parks, markets, and residential compounds. It also serves as a major source of shade for petty traders whose stalls are usually around the neighbourhood (Pitan *et al.,* 2000). Mango Mealybug, *Rastrococcus invadens*, infestation is a major problem and a great concern to both the farmers and non-farmers alike. The mealybugs are usually found on the underside of the leaves, causing damage directly on mango leaves by sucking plant sap. The insect was first discovered in Abeokuta in 1989 and was believed to have been introduced mainly from Lagos and Republic of Benin as both share borders with Ogun State.

For its control, an encyrtid exotic parasitoid, *Gyranusoidea tebygi*, which originated from India, was imported, reared and released nation-wide. About 280 adult *G. tebygi* were released on 10th August, 1989 on mango trees in Ijebu-Ode, Abeokuta and Shagamu in Ogun State (Pitan *et al.,* 1999). Monitoring surveys carried out between 1994 and 1998, revealed the establishment of the parasitoid in all the agro-ecological regions of the country. At Abeokuta for example, the mealybug population density on mango crashed from 49 adults per leaf recorded in 1994 to zero in 1998 resulting in improved mango fruit production (Pitan *et al.,*2002). However, in 2012, mango mealybug was spotted on mango trees at many locations in Abeokuta which later became wide-spread from 2014 (Pitan O.R, *Pers. Com*). The objective of this study was therefore to determine mango mealybug status, current infestation levels and the status of the existing natural enemies of the mealybug in Nigeria.

MATERIALS AND METHODS

Monitoring surveys were carried out between May and June, 2021 in Abeokuta metropolis: Idi-Aba, Iyana Mortuary, Asero, Obantoko, Federal University of Agriculture Campus, and Adigbe (Plate 1). Sampling was carried out along the roads and four host plants: *Mangifera indica, Citrus* spp. *Plumeria alba* (Frangipani), *Ficus* spp (fig) were selected every 100 m. At each stop, all plants in the vicinity were critically examined for the presence or absence of the mealybug including the life stages. Only the plants with the life stages of *R. invadens* were considered as hosts.

Ten leaves were randomly selected from five different points on each plant species and the leaves were examined using a hand lens. The data collected were; (a) number of mealybugs; (b) number of mummified mealybug and (c) number of predators. Parasitized mealybugs (mummies) were removed from the leaves with a camel hairbrush and kept in tagged transparent sample bags until the emergence of parasitoids and/or hyperparasitoids. Mummies with emergence holes were discarded after counting and records of the number of parasitoids emerging from each sample bag was kept. They were then removed and preserved in 70% alcohol while some were mounted for identification purposes.

After 3 weeks, all the mummies from which there were no evidences of emergence were collected from the sample bags and kept in alcohol for 24 hrs to soften. They were later dissected and the insects found in the cases were identified and recorded. By so doing, all the mummies were accounted for and parasitism indices were calculated based on these data. Predators were also counted and were later kept in 70% alcohol for preservation.

Severity of infestation on the host plants was based on the number and proportion of foliage and twigs showing only the mealybug and sooty mould together where:

Light	=	<25% of the foliage of the host plant shows infestation by the mealybug and often on the abaxial surface of foliage only. (+)
Moderate	=	25 – 50% of the foliage of the host plant shows infestation by the mealybug. (++)
Heavy	=	> 60% of the foliage of the host plant shows mealybug infestation together with sooty mould on both surfaces of foliage. (+++).
Very heavy	=	entire foliage, twigs, inflorescences and sometimes fruits, are covered by the mealybug and sooty mould. (++++)

Plate 1. Map of Ogun-State Showing Abeokuta metropolis where samples were taken
Source: Adekunle *et al.,* 2019

RESULTS

Distribution of *Rastrococcus invadens* in Abeokuta metropolis

During the surveys, the mealybug was observed only on mango trees at all the sampling locations: Idi-Aba, Iyana Mortuary, Asero, Obantoko, Federal University of Agriculture Campus, and Adigbe. About 94% of all the mango trees sampled were infested with the mealybug. The mean mealybug population density was 37.6/leaf, while percent parasitism was 3.0 (Table 1). Out of this, primary parasitism was 58.4% with *G. tebigy* and *Anagyrus aurantifolis* contributing 35.6 and 22.5%, respectively. However, secondary parasitism was 41.6% with *Leopardina* sp. and *Chartocerus* sp contributing 20.6 and 21% respectively (Table 1).

Table 1. Percent mealybug parasitism as recorded on mango trees in selected locations at Abeokuta

Parameter	Value
Mean mealybug/leaf	37.6
Mean no of mummies/leaf	1.1
Percent Parasitism	3.0
Gyranusoidea tebygi	35.6
Anagyrusaurantifomis	22.8
Primary parasitism	**58.4**
Leopardina sp.	20.6
Chartocerus sp.	21.0
Secondary parasitism	**41.6**

DISCUSSION

In this study, mango mealybug was not recorded on any other host plant apart from mango trees unlike in 1988 when the insect pest was first reported in Abeokuta, many ornamentals, fruit trees and shade trees served as its hosts (Pitan *et al*., 2002). This indicates that the pest has been adequately regulated as has been reported in several other parts of Africa where as soon as the parasitoids were released, mango trees became the only host (Bokonon-Ganta *et al.,* 1988; Agounke *et al.,* 1989; Neueschwander *et al*., 1995). The percentage of infected trees appear rather to be too high considering the fact that the exotic parasitoid, *G. tebygi*, has established in Nigeria. In Abeokuta metropolis for example, the released parasitoid caused a drastic reduction in the mealybug density, while mealybug extinction and significant improvements in mango fruit production were all reported (Pitan *et al* 2001; Pitan *et al.,* 2002). Similarly, the intensity of mealybug infestation recorded in this study which is 37.8/leaf is comparable with earlier report of 49.0/leaf when the mealybug was first introduced into Nigeria in 1989 (Pitan *et al*., 2002). Surprisingly, percent primary parasitism recorded was 58.4 with the released *G. tebygi*contributing 35.6% and the local parasitoid *A. aurantifolis* contributing 22.8%. Compared to earlier reports these values are getting lower for *G. tebygi* and higher for *Anagyrus* indicating a high-level competition between them. Also, the high level of hyperparasitoid activity recorded on the parasitoids in this study is unprecedented and could be taken that the released *G. tebygi* has faced some ecological pressure over the years and would have to be re-investigated for bio-efficiency in the context of its interactions with the immediate community. Such interaction to consider for investigations may include changes in the biochemical composition of the secondary metabolites and/or the nutritional value of the mango tree, changes in parasitism and /or direct effects on the mealybug such as fecundity stimulation and increased growth rate (Pitan, 2008).

The socio-economic implication of the mealybug resurgence is that the infestation may become more severe if not controlled, and may result again in severe reduction in the yield of fruits and vegetables, and ultimately in the output from industries that process these crops. The socio-economic consequences of severe reduction or near complete loss of infested fruits and vegetables are grave on the nation, because much of the population depends on them as ready sources of cheap energy, vitamins and minerals. The aesthetic and socio-cultural values that make shade trees and ornamentals converging points for rural meetings, entertainment, and also rural and urban leisure are seriously undermined. This is because infestation renders plant canopies unsightly and unacceptable and the associated ants and flies that feed on the honeydew are also repulsive (Pitan *et al*., 2000).

CONCLUSION

In conclusion, the resurgence of mango mealybug was confirmed in the locations where the survey was carried out in Abeokuta. The infestation status is also high as 37.6% adult mealybug was recorded per leaf. The study also revealed the presence of both the exotic and local natural enemies, as well as hyperparasitoids.

RECOMMENDATION

Being exotic and polyphagous, *R. invadens* is a good candidate for biological control, however, the efficiency of *G. tebigy* has declined over the years. In other to address this, augmentation of existing population of *G. tebigy* can be done. Secondly, it is also important to understand the factors regulating its abundance with respect to current realities of climate change.

ISSN: 2814-0508

Since the exotic parasitoid has been released, it is important to properly study the natural enemy with respect to current realities such climate change and their ability to control the pest determined before any consideration is given to the introduction of another one. If the existing ones are really suppressing the population of the mealybug for instance, then there is no need for a new introduction; only the augmentation of the existing population would then be necessary to effectively control this insect pest.

ABSTRACT

Black pod disease caused by P. Palmivora and P. megakarya is an important disease affecting cacao in West Africa which produces 70% of the world output. Resistance to the pathogen is therefore, an important factor to be considered when breeding for high yielding and earliness in fruiting. Resistance to the pathogen using Leaf Disc Test (LDT) was conducted at the Plant Pathology Laboratory, Ibadan, on detached 15mm diameter discs of two-month-old leaves obtained from nineteen newly generated cacao hybrids in the gene pool of the Institute. Attached Whole Leaf Test (AWLT) was also conducted on few selected hybrids in the screen house at the same institute. Ten µl zoospores suspension of P. megakarya pathogen adjusted to inoculum strength of $3x10^5$ zoospores/ml using haemocytometer was used for the inoculation of the cacao LD. Using 0-5 disease rating scale, data was taken on the 5^{th} and 7^{th} day after inoculation for LDT and on the 6^{th} day after inoculation for AWLT. Data obtained were subjected to Analysis of Variance and significant means were separated using Student Newman Kuels Test at $p<0.05$. The LDT classified the hybrids into five groups namely: Resistant (hybrid 001, 003 and 005); Moderately Resistant (hybrid 006, 007, 008,013,015,018 and 019) Moderately Susceptible (hybrid 004, 014 and 017); Susceptible (hybrid 002, 010, 011 and 016) and Highly Susceptible (hybrid 009 and 012). Scores from LDT significantly correlated ($r= 0.92^{**}$) with that of AWLT. It was observed from the study that cacao hybrid 001, 003 and 005 showed traits of resistant and therefore, could be incorporated into the national breeding programs for the development of high-yielding and resistant cacao cultivars. The moderately resistant hybrids could be conserved for future germplasm enhancement program.

Key words: *P. palmivora*, *P. megakarya*, *cacao* hybrids, LDT, AWLT, breeding, resistance group, black pod disease

INTRODUCTION

Cacao (*Theobroma cacao* L.), an understory tree belongs to the order Malvales and family Malvaceae (Wickramasurya and Dunwell, 2018). It is an important cash crop cultivated for its nutritional value and industrial uses locally and internationally (Nyadanu *et al*., 2012). Fourteen states in Nigeria namely Ondo, Cross River, Osun, Ogun, Ekiti, Edo, Abia, Adamawa, Taraba, Akwa Ibom, Delta, Kogi and Kwara were reported to produce 95% of country's export (Famaye, 2013). Reports showed that eight hundred thousand (800,000) hectares of Nigeria arable land were under *cacao* cultivation between 2003 – 2005 (ICCO, 2008). Cocoa production in Nigeria, due to several factors has failed to meet the demand from local and international consumption and processing. Prominent among these factors is the difficulty in the attainment of optimal yield from this tree crop despite the increased acreages largely due to cacao diseases.

Several pathogens attack *cacao*, but one of the most important diseases of *cacao* in Nigeria is the black pod disease caused by *Phytophthora* spp. Two of the several species of the black pod pathogen namely *P. palmivora* (less than 20% distribution) and *P. megakarya* (over 80% distribution) have been identified as the causal agent of the disease in Nigeria (Akrofi, 2015). Of these two species reported on *cacao* in Nigeria, *P. megakarya* was noted to be more virulent and has been reported to displaced *P. palmivora* over period, but the strategy involved is not clear (Ali *et al*., 2017).

In Nigeria, 30% yield and crop losses due to *P. palmivora* was reported (Okaisabor, 1965) while 80% losses in *cacao* and its produce due to *P. megakarya* was reported in unkempt farms (Agbeniyi and Adedeji, 2003). In wetter part of the country, 90-100% yield losses were also recorded (Maddison and Griffin, 1981). Estimated annual yield losses of 700,000 metric tons of cocoa was reported globally due to black pod disease (Ploetz, 2016). Cultivation of susceptible varieties and the prevailing environmental conditions are factors that influence the disease (Adegbola, 1981).

Although chemical control is possible, it is expensive (Vis-a-vis 400kg/ha production) and require skills for effective application, couple with the Problem of chemical residue and environmental hazardousness (Crig, 2010). Screening for resistance to select cultivars that are resistant to the disease for field establishment has been advocated as the environmentally safe, relatively cheap and best disease management measure (Iwaro *et al*., 2005 & 2006; Surujdeo-Maharaj *et al*., 2001).

Therefore, this study was conducted to determine the resistance status of some newly generated cacao hybrids to black pod pathogen using leaf disc and attached whole leaf tests.

MATERIALS AND METHODS

Nineteen newly produced cacao hybrids (Table 1) from a new cacao breeding research plot (7° 13'N, 3° 51'E) at Cocoa Research Institute of Nigeria (CRIN), Ibadan were used for the study in 2016. Detached Leaf Discs Test (LDT) and Attached Whole Leaf Test (AWLT) were employed for black pod resistance screening in CRIN plant pathology laboratory and greenhouse respectively. Genotype C77 and Pa150 were used as resistant checks while Genotype N38 and ICS1 were used as susceptible checks

Leaf Discs Test (LDT)

Healthy young lignified cacao leaves of approximately two-month-old were obtained from the selected hybrid plants (Table 1) at CRIN headquarters, Ibadan for the study. Leaf discs (LD) were prepared, arranged, inoculated and incubated as described by Nyassé *et al*., 2002 & 1995; Tahi *et al*., 2006 and Nyadanu *et al*., 2012. Inoculum was cultured, prepared and standardized to 300,000 mL^{-1} as described by Tahi *et al*., 2006, Nyadanu *et al*., 2012 and Tijani, 2018. *Phytophthora* species used for the study was identified as *P. megakarya* according to Stamp *et al*., 1990. Data were collected on the 5th and 7th day of inoculation to described levels of infection of the LD using five-point disease assessment (rating) scale as described by Nyassé *et al*., 1995 and Nyassé 1997.

Attached Whole Leaf Test

Attached leaves that correspond to about two months old leaves were inoculated with zoospores suspension (prepared and standardised as described for LDT) on selected *cacao* seedlings in the greenhouse. Eight (8) hybrids were randomly selected such that at least one hybrid represents each resistance class and replicated three (3) times. Two attached leaves were inoculated on each seedling which amounts to six (6) leaves per genotype for the eight (8) hybrids. Ten (10) points were inoculated at the underside of each selected leaf along the midrib which amounts to sixty (60) inoculated points per hybrid. Inoculation was carried out by using a sterile automated repeatable dispenser attached to a micro-syringe (Eppendorf) to deliver 10µl droplets of the zoospore suspension on each inoculation point, at a right angle along the leaf midrib. The greenhouse was maintained at 26 ± 2°C air temperature provided by digital Samsung air conditioning unit and approximately 80% relative humidity was provided by transparent polythene bags for the 6-day incubation period.

The inoculated leaves were inspected for lesion appearance, 6th day after inoculation and data were recorded on their reaction to black pod pathogen using a five-point disease assessment scale as described above. Both the Leaf Discs Test (LDT) and Attached Whole Leaf Test (AWLT) were repeated twice.

Statistical analysis

Data obtained on the frequency and spread of lesions in LD and AWL were subjected to analysis of variance (ANOVA) using SAS (Statistical Analysis System) software. Significant means were separated using the Student Newman Kuels Test (SNK) at $p<0.05$. Means obtained from leaf disc scores (for selected lines) were correlated with that of attached whole leaf to confirm the reliability of leaf disc test at $p<0.05$.

RESULTS

Evaluation of LD and AWL of the cacao Hybrids for resistance to *P. megakarya* isolate(s):

The result of the study showed that the newly produced cacao hybrids reaction to *P. megakarya* isolate(s) varied significantly with respect to the various lesion sizes induce on LD's, (Table 1). Mean disease severity quantified by the lesions on LDs of the various cacao hybrid showed that hybrid 5 has a lowest mean disease score of 1.22 followed by hybrid 3 with a disease mean score of 1.31 and then the resistant check genotype Pa150 with a mean score of 1.33. The N38 control cacao genotype however had the highest disease mean score of 2.27 followed by cacao hybrid 12 with disease mean score of 2.17 and then the ICS1 and cacao hybrid 9 with disease mean scores of 2.15 and 2.14 respectively. Analysis of variance

ISSN: 2814-0508

(ANOVA) done for LD's lesion scores in their reaction to the *P. megakarya* isolates, (Table 1), shows that the resistance of newly generated cacao hybrids varied significantly at p<0.05. Significant means were separated using Student Newman Kuels (SNK) Test and classified as shown in Table 1. At p<0.05, there was no significant difference in the reactions of cacao hybrid 3, 5 and the resistant check cacao genotype Pa150 to the *P. megakarya* isolates and are classified as resistant. The cacao hybrid 1 reacts significantly different but closer to others in resistant category, thus classified as resistant. However, the reaction of these cacao hybrids and genotype to the *P. megakarya* isolates significantly varied with the other cacao hybrids and genotypes. Cacao hybrids 6, 7, 8, 13, 15, 18 and19 did not differ either in their reaction to the *P. megakarya* isolates but varied significantly in their reaction when contrasted with the other cacao hybrids and genotypes, hence classified to be moderately resistant. The other cacao hybrids and genotypes reaction to the *P. megakarya* isolates varied from moderate to been highly susceptible.

In the AWL assay, Pa150 has the lowest mean lesion score of 0.95 followed by cacao hybrid 5 and 1 with mean lesion score of 1.14 and 1.15 respectively. N38 cacao genotype had the highest mean lesion score of 1.94 followed by cacao hybrid 9 with 1.84 and then ICS1 cacao genotype with lesion mean score of 1.71 (Table 1). ANOVA ran for disease mean score on attached leaves showed significant variations in the various reactions of the cacao hybrids and the check (control) genotypes. At p<0.05, Pa150 significantly varied in its reaction with the other cacao hybrids and genotypes and was classified as highly resistant. Cacao hybrid 5 and 1 did not vary in their reaction to the *P. megakarya* isolates but significantly varied in their reaction to *P. megakarya* isolates when compared with the other cacao hybrids and genotypes and are classified as resistant, (Table 1). Cacao hybrid 7 also differed significantly in its reaction with the other cacao hybrids and genotypes and was classified as moderately resistant. The other cacao genotypes and hybrids' reaction to *P. megakarya* showed various reactions that ranged from moderately susceptible to susceptible. A good correlation was found between LD and AWL score means at p<0.05 (r= 0.93**).

DISCUSSION

The study shows the intrinsic variable genetic qualities existing among cacao hybrids assayed for resistance to black pod disease in the gene pool of CRIN. The mean lesion score of the disease severity in the detached LD assay of the cacao hybrids showed that none of the hybrids was totally immune to the black pod pathogen. This observation is in agreement with earlier reports of Lawrence (1978) and Omokolo *et al*. (2003).

It was also observed in the detached LD assay in the study that the cacao hybrid 3 and 5 showed resistance to the *P. megakarya* pathogen which was not significantly different from the resistant control, Pa150 which is of the Forastero group and an Upper Amazonian cacao genotype. This finding is in agreement with the reports of Iwaro et al., 2006 and Otuonye, 2009 who reported that the Forasteros groups, which include the Amazon cacao genotypes, are made up of higher percentage of moderately resistant to resistant genotypes. It was also noted that Trinitarios, been hybrid progeny between Criollo and Forastero are highly heterogeneous in their resistant character. This may be responsible for the observed reactions of the cacao hybrids to *P. megakarya* black pod pathogen.

The study also showed that seven (7) cacao hybrids with Forastero, Amazon and Trinitario pedigree showed moderate resistance to the *P. megakarya* pathogen. This conformed with the findings of Iwaro et al., 2006 and Otuonye, 2009 who also reported resistance to *P. megakarya* pathogen for cacao genotype T12/11 and T86/2, both Upper Amazon cacao genotypes, crossed to obtain parents for some of the hybrids that showed resistant and moderate resistant respectively to *P. megakarya* pathogen. Reports from Toxopeus, 1967, Akaza *et al*., 2009 and Nyadanu *et al*., 2012 showed that T12/11 and T86/2, Sca6, T60/887, Pa150, P7 and Pa7/808 were used as crosses for some of the parents of the hybrids and resistant control as black pod disease resistant/escaping clones. In Cameroon, highest resistance to *Phytophthora* pod rot was also reported for hybrid P7 x Pa150 using LD assay which was correlated with highest resistance obtained in the field with this cacao genotype (Nyassé *et al*., 2003; Efombagn *et al*., 2011).

Table 1. Mean lesion score of black pod disease induced by *Phytophthora* spp on the cacao hybrid LD and AWL with their degree of resistance

Means in the same column not followed by the same letter are significantly different according to Student Newman Kuels (SNK) Test at 5% probability level

It was observed from the detached LD assay in this study that nine (9) of the cacao hybrids with Forastero, Amazon and Trinitario pedigree showed moderate susceptibility to high susceptibility class with none of the cacao hybrids however, showing worst reaction when compared with the susceptible control ICS1 and N38 genotypes. The observation is in agreement with the findings of Tahi *et al*., 2000, Aikpopodion, 2007 and Otuonye, 2009 who reported that variation in character expression in cacao progenies given the Quantitative trait loci (QTL) of the parents of a progeny may involve either of the parents in character expression if they favorably share a common alleles brought by both or the character expression may involve each individual parent where it is not shared. They also noted that the variation in character expression between and within clones and progeny families may be due to segregation of the genome in response to resistance. Forastero is a very variable group and consist of the lower Amazon (West African 'Amelonado', 'Maranhoa', 'Comun' and 'Para' types from Brazil) and the Upper Amazonian cocoas (Costè, 1992). The lower Amazonian cacao genotypes for example, the West African 'Amelonado' are known for their susceptibility to the black pod disease. The out-breeding nature of cacao which is responsible for a high level of heterogeneity may bring about resistant variation observed in Trinitarios, been a hybrid between Forastero and Criollo (Iwaro *et al*., 2006). The variation in character expression by these cacao hybrids may be due to an involvement and expression of alleles of an individual of the parents in the QTL. This may account for the variation observed in the resistant character expressed by these cacao hybrids to the *P. megakarya* pathogen.

In the AWL assay, a high resistant trait was expressed by Pa150 in the study confirming its reliability as a resistant check. This observation was same for all the cacao hybrids and control genotypes selected for the AWL assay. It was observed for example that cacao hybrid 4 that showed susceptibility in the detached LD assay showed moderate susceptibility in AWL assay. This finding is in conformity with the findings of Iwaro et al., 2006 and Otuonye, 2009 who reported that susceptibility is generally higher in detached leaves and pods than in the attached organs. This may be responsible for the observed reaction of the AWL of the cacao hybrids to the *P. megakarya* pathogen.

The insignificant isolate x host interaction has been reported from the findings of Nyassé *et al*., 1995, Van Der Vossen, 1997, Surujdeo-Maharaj *et al*., 2001 and Nyadanu *et al*., 2012 established *Phytophthora* species non-specificity with cacao genotypes. This indicates that cacao hybrids resistance in this study to *P. megakarya* could be applicable to other *Phytophthora* species causing pod rot of cacao in the other areas of cocoa production in the world.

It was observed also from this study that C77 cacao genotype which was once used as resistant control (Otuonye *et al*., 2006; Otuonye, 2009) showed moderately susceptibility to the *P. megakarya* pathogen. This finding points to the fact that there may be changes in the population of the *P. megakarya* pathogen on cacao in Nigeria, indicating the possible diversity in the genetic make-up of the pathogen with the appearance of more virulent strains that enable it to breakdown the resistance of C77 cacao genotype and cause enormous losses in revenue for the cocoa industry. This point to the need for continuous rapid screening of cacao germplasm using leaf disc assay, which have been proven to be reliable, cheap and fast in the selection and enhancement of germplasm for resistance to black pod disease.

A good correlation obtained between detached LDT and the AWLT in this study showed the reliability of the detached LD assay as an effective screening method that could be used to predict cacao genotypes reaction and resistance in the field to *P. megakarya* pathogen.

CONCLUSION

This study revealed that some of the cacao hybrids used in this study had innate resistant trait against *Phytophthora* pathogen, the causal agent of black pod disease of cacao, in the gene pool of CRIN. Of the nineteen cacao hybrids screened, three (3) were found to be resistant, seven (7) were found to be moderately resistant, four (4) were found to be moderately susceptible, three (3) were found to be susceptible and two (2) were found to be highly susceptible. C77 cacao genotype which was previously reported and consequently use as resistant check was found to be moderately resistant in this study, thus appearing to be losing its hitherto resistant status. While the reliability of Pa150 as resistant check remained intact. The resistance in attached leaves of cacao hybrids is higher than that of the detached leaves.

RECOMMENDATION

Cacao hybrid 1, 3 and 5 which were classified to be resistant in this study, are suggested for selection in cacao breeding activities for resistant varieties. These could be recommended for incorporation into national breeding program for distribution and developing high yielding disease resistant cacao cultivar. While hybrid 4, 7, 8, 13, 15, 18 and19 which were found to be moderately resistant could be conserved for future germplasm enhancement program.

ABSTRACT

Cacao is an economic cash crop grown in many countries across the world, with Côte d'Ivoire, Ghana, Indonesia and Nigeria as the leading producers. Prominent among the major constraints against cocoa production in Nigeria is the problem of plant-parasitic nematodes, which though often confused with other infections, has led to substantial decline in production. The presence of multiple pathogens has made correct diagnosis and estimation of impacts of nematodes on cocoa somewhat difficult. This has expectedly led to adoption of erroneous control measures on the crop. Among all known nematode species, Meloidogyne incognita has been found to be of economic importance on cocoa, particularly in West Africa (including Nigeria), India, Malaysia, Venezuela and Brazil. Other species found on cocoa include M. exigua (Bolivia), M. javanica (Malawi, Venezuela and Central Africa), M. arenaria and M. thamesi (Brazil). M. incognita has been found, through experimental studies, to cause dieback, stunting, wilting, yellowing of leaves and reduction in leaf size. Pathogenicity of some other nematode species has also been confirmed by scientists. Both chemical and non-chemical methods have been used for effective management of these hidden enemies of cacao across the globe. However, non-chemical method, involving the use of organic soil amendments, is safer and cheaper for the poor resource farmers.

Keyword: Cacao, plant-parasitic nematodes, root-knot nematodes, dieback

INTRODUCTION

Cacao (*Theobroma cacao* Linnaeus) plays important roles in the agricultural sector of the Nigerian economy. The crop contributes significantly to food security, employment, diversification of income sources in rural and urban areas, and contribution to the gross national product. Cacao is cultivated in many countries of South and Central America, Africa, Asia and Oceania, located mostly between 10^0 North and South of the Equator. The principal cacao-growing countries of West Africa, namely Côte d'Ivoire, Ghana, Nigeria, Cameroon and Togo make up about 70 per cent of the world's cocoa production (Simo *et al*., 2018). Nigeria is the world's fourth largest cocoa producer, after Indonesia, Ghana and Cote d'Ivoire. It may be possible to produce cocoa beans in volume in other regions, but to replicate the unique flavour; the chemical and physical characteristics of the West African cocoa may prove to be very difficult (WPR, 2021; Taylor and Taylor, 2006).

Although cocoa farmers in the country are aware of the need to improve the productivity of the crop, pests have been a major constraint. Plant-parasitic nematodes constitute a major barrier to production accounting for a rapid decline in adult cacao productivity and establishment of seedlings in fresh and rehabilitated fields (Orisajo, 2018, Orisajo et al., 2012).

One difficulty with assessing nematode impact is that damage resulting from nematode infection is often less obvious than that caused by many other pests or diseases. Because of the ubiquitous interaction of nematodes with other pathogens, the concept of economic threshold, so well established for many crops and pathogens in temperate environments, is difficult to establish under field conditions in tropical regions. The presence of multiple pathogens makes diagnosis confusing and frequently results in underestimation of the damage caused by nematodes. The masking effects of damage caused by nematodes also can lead to the adoption of erroneous control measures, particularly in annual crops (Orisajo, 2012). For example, root-knot nematode attacked cacao seedlings leading to dieback (Figure 1), but farmers erroneously thought it was a fungal infection. Losses that result from nematode attack may not necessarily be as a consequence of direct cell death, necrosis or 'diseased' tissue but may derive from other more insidious aspects, such as interference with the root system, reducing their efficiency in terms of access and uptake of nutrients and water. Nematode-affected plants often present typical drought and nutrient stress symptoms, which are easily and often misdiagnosed (Okeniyi et al., 2009).

PLANT PARASITIC NEMATODES OF CACAO

Root-knot nematodes, *Meloidogyne* spp., are the most important nematodes of cacao due to their pathogenicity and wide distribution in cocoa producing regions of the world (Campos and Villain, 2005). *Meloidogyne* spp. have been found in cacao since 1900 and have been reported from Zaire, São Tomé, Java, Ghana, Malawi, Côte d'Ivoire, Nigeria, Venezuela, Brazil and India (Okeniyi et al., 2009).

Meloidogyne incognita seems to be the most frequently found in cacao. It is a common pest in West Africa, including Nigeria, where this species appears as the most economically important nematode on cacao. *M. incognita* is also common in India, Malaysia and Venezuela and is widespread in cacao regions of Brazil (Fademi et al., 2006). However, other species of *Meloidogyne* have also been found on cacao: *M. exigua* in Bolivia, *M. javanica* in Malawi, Venezuela and in Central Africa, and *M. arenaria* and *M. thamesi* in Brazil (Crozzoli et al., 2001).

Other root-feeding nematodes of cacao include *Hemicycliophora* spp. (Thorne) Entwistle & Caveness, *Hoplolaimus* spp., *Radopholus similis*, *Rotylenchulus reniformis* Linford & Oliveira, *Scutellonema brachyurus* Steiner, *Trichodorus* spp. Allen, and *Xiphinema* spp. (Cobb) Luc. *Helicotylenchus* spp. are widespread on cacao in South America and Asia, and *H. pseudorobustus* reproduced on cacao in Liberia. *H. dihystera* was reported in Bahia State of Brazil as the most widespread species on cacao, occurring in 70% of the samples. Afolami and Caveness (1983) reported the frequency of occurrence and geographic distribution of plant-parasitic nematodes associated with cacao in Nigeria. The common genera found were *Helicotylenchus*, *Hemicycliophora*, *Meloidogyne*, *Radopholus, Scutellonema*, *Trichodorus* and *Xiphinema* (Lamberti et al., 1992).

SYMPTOMS OF ROOT-KNOT NEMATODE DAMAGE ON CACAO

In artificially-infected seedlings, *M. incognita* caused dieback, stunting, wilting, and yellowing of leaves and reduction in size of leaves. Tiny galls, juveniles and females of *M. incognita* with egg masses can be observed on the roots (Fig. 2). In Nigeria, seedlings of cv. Amelonado grown in soil inoculated with *M. incognita* showed the symptoms from the 16th week, leading to wilting in the 24th week. Amazon cultivars also showed symptoms, but only after the 24th week, and without wilting. In the field, *M. incognita* produces galls with exposed egg masses on roots, dieback and sudden death of the infested plants (Orisajo et al., 2007). According to Sharma and Sher (1973), when the dieback conditions occur, the trees die down to their roots, which remain alive and send up shoots in the next growing season and also when the dead terminals are pruned off (Fig. 1). The syndrome of sudden death disease is permanent wilting, the green leaves suddenly turn yellow and brown, and they dry up to remain hanging (Fig. 3). Sharma and Sher (1973) associated the occurrence of sudden death

ISSN: 2814-0508

with root-knot nematodes. Campelo and Galli (1980) demonstrated the pathogenicity of *Helicotylenchus* spp. on *T. cacao*. A significant reduction was observed in dry root weight and leaf number in 20-day-old inoculated seedlings.

MANAGEMENT OF PLANT-PARASITIC NEMATODES

Control of nematodes in perennial crops is more difficult than in annual crops. The long-time nature of perennial crops makes rotation schemes impractical. In perennial crops such as cacao, nematodes that survive the control practices have time to recover and build up again to destructive levels. Nematode control, therefore, becomes essential in order to reduce crop losses and to ensure self-sufficiency in the requirements for food and industrial raw materials. Several nematode control options are available. These can broadly be categorized into chemical and non-chemical control methods. The latter includes good farm hygiene, use of heat and organic amendments while the former essentially, involve the use of nematicides.

Chemical Control

Historically, nematicides have been highly effective and reliable in controlling a wide range of nematode species in certain crop situations. The advantages to be derived are quick effects on the plant-parasitic nematodes leading to spectacular increases in yields, especially of high-valued crops. Sosamma *et al.* (1980) have reported an increase in the number of cocoa pods by the application of Dasanit, Nemacur and Carbofuran. However, these nematicides have been banned on cocoa (Bateman, 2008) due to negative shifts such as

ISSN: 2814-0508

health hazards, environmental pollution and potential atmospheric ozone depletion (Ghorbani et al., 2008). Hence the need to look for alternatives to chemical control.

Organic Amendments

The addition of organic amendments that stimulate growth of antagonistic microorganisms, or release toxins during decomposition has been advocated as an alternative method to chemical control of plant-parasitic nematodes. The application of organic material as soil amendment, though a traditional practice to improve soil fertility and structure, is also known as a control method for soil- borne diseases, including plant-parasitic nematodes (Houx *et al*., 2014). In recent years, a variety of organic materials, such as animal and green manures, compost, and proteinaceous wastes, are used for this purpose (Atandi et al., 2017, Shiferaw et al., 2017, Briar et al., 2016; Forge et al., 2016). Incorporation of organic amendments has been shown to be detrimental to plant-parasitic nematodes (Wang et al., 2004) due to release of NH4, formaldehyde, phenol, volatile fatty acids and toxic compounds (Briar et al., 2016). It was generally postulated that the adverse influence of organic amendment on plant-parasitic nematode is referred to increasing host resistance to nematode infection and enhancement of growth performance (Country & Millon, 2008). Therefore, soil amendment with water leaf extracts of *Acalypha ciliata, Jatropha gossypifolia, Azadirachta indica* and *Allium ascalonicum have nematicidal effects* on *Meloidogyne incognita* thereby reducing infection on cacao seedlings (Orisajo et al. 2007). Also, soil incorporation of goat dung, organo-mineral fertilizer and organic fertilizer at 200 kg/ha have been shown to enhance growth, survival and field establishment of cacao seedlings in the soil infected with plant-parasitic nematodes (Orisajo and Adejobi, 2020). Poultry litter compost soil amendments at 5% also have potential for suppressing *M. incognita* populations on cacao seedlings in the nursery (Meyer *et al*., 2011).

CONCLUSION

Plant-parasitic nematodes have remained important hidden enemies of cocoa productivity in virtually all known cocoa producing countries of the world. Their impacts on the cash crop have, often times, been confused with some other pathogenic infections. Improving the agronomic conditions for plant growth is an important factor for increasing the plant tolerance to plant-parasitic nematodes. Therefore, soil application of organic amendments is recommended for effective management of these hidden enemies of cacao and enhancement of field establishment.

ABSTRACT

Field trial was carried out in 2013 and 2014 early seasons at the National Horticultural Research Institute, Ibadan to determine the effect of poultry manure amendment on tomato fusarium wilt incidence and severity and to also determine the relationship between disease incidence and the growth parameters. The experiment was laid out in a Randomized Complete Block Design with three replications. Treatments include two tomato varieties (Roma VF and Ibadan local) and four levels of poultry manure (0, 6,12 and 18 tons/ha). Data collected on disease incidence and severity, plant height, fruit number, fruit weight among others were subjected to Analysis of Variance and means were separated using Least Significant Differences at p<0.05. in both years, the result showed that poultry manure induced disease that ranged between 38-57 % and 20 – 57 % in Ibadan –local and Roma VF respectively. While severity reduction of 28-54 % was recorded in Ibadan local variety Roma VF had severity reduction that ranged between 29-58 %. Overall assessment showed that poultry manure at 18tons/ha had the highest Fusarium wilt reduction of 56% and 59% in Ibadan local and Roma VF respectively. Therefore, Poultry manure application at 12 tons/ha should be encouraged for Fusarium wilt incidence reduction and for enhanced fruit yield.

Key words: Fusarium wilt, poultry manure, management. tomato

INTRODUCTION

Organic amendment such as animal manure improves soil structure and fertility and decrease the incidence of disease caused by soil borne pathogens (Noble and Coventry, 2005). In the past century, the introduction of synthetic inorganic fertilizers, disease-resistant varieties and fungicides has allowed farmers to break the link between organic amendments and soil fertility (Hoitink and Boehm, 1999). As a result, organic materials such as crop residues and manure from essential resources became solid wastes. After the reduction of the organic input, soil organic matter decreased over time, soil fertility declined, and a large number of diseases caused by soil borne plant pathogens spread in agro-ecosystems (Bailey and Lazarovits, 2003). However, a renewed interest in application of organic matter to soil, for soil for the management of soil borne pathogens has gained public interest because of the adverse effects of soil fumigants and fungicides on human and the environment, hence the need for healthier environment and agricultural products (Lazarovits *et al*., 1999). Poultry manure is a good depositor of major and minor mineral elements that are capable of enhancing soil fertility on application. It also acts as a substrate for soil microorganisms and increases microbial activities, thereby decomposing faster and releasing nutrients above plant uptake levels (Thomas, 1997). Additionally, amending soil with decomposable organic matter is a viable option in pathogen suppression as it changes the soil and rhizosphere environment and enriching the soil with microflora potentially competitive or antagonistic to pathogens or release inhibitory substances or volatiles during decomposition (Hoitink and Fahy, 1986). The aim of this was to determine the effects of different rates of poultry manure as soil amendment on incidence and severity of tomato Fusarium wilt under field condition.

MATERIALS AND METHODS

Experimental site

Field experiment was conducted at the NIHORT vegetable experimental block between June and October in 2013 and was repeated using the same field, in the same period in 2014. The field was endemic to *Fusarium oxysporum* f.sp. *lycopersici* from the history. The experiment was laid out in a Randomized Complete Block Design with three replications. The treatments included two tomato varieties; Roma VF (moderately tolerant) and Ib-local (moderately susceptible) and four levels of poultry manure (0, 6, 12 and 18tons/ha). The plot size of 3 m x 3 m (9 m^2) was separated by 0.5 m and 1 m from other plots and blocks respectively. Tomato seedlings were transplanted in 5 rows at spacing of 0.75 m between rows and 0.5 m within rows. The total experimental area was 30 m x11 m (330 m^2). Cured poultry manure was

ISSN: 2814-0508

manually incorporated into the soil three weeks prior to transplanting of four weeks old seedlings of Ibadan –Local and Roma VF (Plate 1). Weeding was done thrice manually at four weeks' interval. Five plants were tagged randomly from the three inner rows. Data were collected on disease incidence and severity, plant height, fruit number, fruit weigh, fresh and dried shoot and root weight among others and were subjected to Analysis of Variance and means were separated using Least Significant Differences at p<0.05.

Disease incidence was calculated according to the formula:

$$WI = \frac{n}{N} \times 100$$

Where WI = Wilt incidence

n = Number of plants showing wilt symptoms

N = Number of plants per treatment

Percentage severity index (PSI) was calculated using the method described by Cooke (2006).

$$PSI = \frac{\sum (X \times 100)}{NR \text{ x } MCS}$$

Where: X = Score per plant

NR = Number of plant rated

MCS = Maximum score of the scale for each scoring scale

Percentage disease reduction was calculated using formular:

$$\% DR = \frac{DIC\text{- } DIT}{DIC} \times 100$$

Where: DIC = Disease incidence/severity index of control; DIT = Disease incidence/severity index of treated

RESULTS

In both years, poultry manure at different rates significantly (P≤ 0.05) reduced disease incidence on the two tomato varieties. In 2013, incidence recorded in Ib – local amended with poultry manure at rate of 12 and 18 tons/ha were comparable and incidences at these rates were significantly (P ≤ 0.05) lower than recorded at 6 tons/ ha. While highest (74.4 %) disease incidence was recorded at control plot (0 tons/ha), a range of between 41 – 60 % reductions were observed in Ib –local at different rates of manure application in 2013 (Table 1). A significantly (P ≤ 0.05) lower (28.3 %) incidence was observed in Roma VF amended with 18 ton/ha poultry manure in year 2013 while the control plot recorded the highest (62.0 %) disease incidence. Incidences due to different manure rates showed no significant difference (P ≤ 0.05) on var. Roma VF in 2013 but at 18 tons/ha application a significantly (P ≤ 0.05) lower incidence was recorded compared with the control treatment (Table 1). In 2014, wilt incidence due to different application rates of poultry manure were comparable and significantly (P≤ 0.05) lower than incidence recorded in the control plot. At different manure rates, incidence reduction that ranged between 34 – 65 % was observed in Roma VF. Disease severity on Ib – local due to manure rates between 6 – 18 tons/ha were at par in 2013, causing severity reduction that ranged between 41 – 59.0 %. In the same year, severity on Roma VF amended with poultry manure at rate of 18 tons/ha was not significantly (P ≤ 0.05) different from severity obtained at the lower rates. A range of between 33- 56 % severity reductions was recorded on Roma VF at different application rates (Table 2). However, in 2014 a significantly lower (P ≤ 0.05) severity (40.0 %) was obtained at 18 tons/ha causing 55.0 % severity reduction in var. Ib –local. Although severity at this rate was comparable with severity recorded at 12 tons/ha application. Similar trend was also observed in Roma VF.

DISCUSSION

Soil borne fungal and oomycete plant pathogens are among the major factors limiting the productivity of agro-ecosystems. They are often difficult to control with conventional strategies such as the use of resistant host cultivar and synthetic fungicides. The lack of reliable chemical controls, the occurrence of fungicide resistance in pathogens, and the breakdown or circumvention of host resistance by pathogen populations are some of the reasons underlying efforts to develop new disease control measures (McDonald and Linde, 2002). This study showed that poultry manure had significant effect in reducing disease and enhancing the growth of tomato. The effectiveness and suitability of poultry manure in this study as organic fertilizer could be attributed to high availability of NPK content it contains (Waddington, 1998). In a similar finding by (Noble and Coventry, 2005) incorporating animal and green manure into the soil was found to improve soil structure and fertility and decrease the incidence of disease caused by soil borne pathogens. Several studies have shown that organic amendments can be very effective in controlling diseases caused by pathogens such as *Fusarium* spp. (Szczech and Smolin´ska, 2001). (Noble and Coventry, 2005). Additionally, Umar *et* *al.* (2013) studied the influence of different quantities of farmyard manure (0, 25, 50, 75 and 100 g/ha) on the growth and disease incidence of *Fusarium* wilt on tomato and reported that there was consistently significant reduction in the incidences and severities of tomato wilt due to *Fusarium*, which suggest that it could be beneficial to farmers in the reduction of wilt caused by *Fusarium* for higher yield tomato production in northern Nigeria.

CONCLUSION

The use of organic amendments for soil fertility and to control soil borne plant disease is a viable option due to the fact that it provides several advantages to growers such as reduction in the use of pesticides for plant disease control thus providing both an economic and environmental benefit. Use of organic amendments also provides use for valuable underutilized agricultural by products and improve the quality of the soil.

Table 1. Effect of different rates of poultry manure on Fusarium wilt incidence of tomato varieties in Ibadan in 2013 and 2014 planting seasons

Treatment Manure rate (tons/ha)	Wilt incidence (%)					
	Ib-local			Roma VF		
	2013	2014	Pooled mean	2013	2014	Pooled mean

ABSTRACT

Microbial biomass is a valuable tool for understanding changes in soil properties and analyzing the degree of soil degradation or soil quality. This experiment was carried out to monitor the change in soil microbial biomass carbon, nitrogen and phosphorus under different amendments used in the control of plant parasitic nematode in a plantain plantation. The experiment was conducted at National Horticultural Research Institute (NIHORT) experimental farm. Three plantain varieties (Obino l'Ewai, Pita 14 and Agbagba) were subjected to five nematode control amendments: Carbofuran, poultry manure, dried neem leaves, Glomus mosseae and control. The treatments were laid out in randomized complete block design with three replications. Soil samples were taken annually with respect to the treatment and assessed for microbial biomass carbon, nitrogen and phosphorus using the fumigation-extraction methods. The data were analysed by descriptive statistics and ANOVA at α0.05. Microbial biomass carbon ranged from 267.12-339.38 mg / kg, 249.47-321.83 and 131.73-258 at years 1, 2, and 3 respectively, while the microbial biomass nitrogen was in the order PM > DNL > GM > CARB > CONTROL at 36 months. The study showed that incorporation of nematode control amendment varies the quantity of soil microbial biomass; therefore, influencing the rate of immobilization and mineralization of soil nutrients.

Key words: *Musa* spp, soil microbial biomass, nematode control methods

INTRODUCTION

Banana and plantain (*Musa* spp) are major food crops in sub-Sahara Africa, providing more than 25% of the carbohydrate and 10% of the calorie for over 100 million people (Swennen, 1990; INIBAP, 2002). It contributes significantly to food security in sub-Saharan Africa (Sharock and Frison, 1998). *Musa* has provided humans with food, medicine, clothing, tools, shelter, furniture, paper, and handicrafts. It is also rich in vitamin C, B6, minerals and dietary fibre. Nigeria is the third largest producer of plantain in Africa with annual production of about 2,785,000 tons in 2006 (FAOSTAT, 2010).

One of the major pests of plantain and banana is parasitic nematode which causes toppling and a yield reduction of 30 – 80% worldwide (Duncan, 2005). Plantain parasitic nematode had been controlled using organic and inorganic substances and it was established that soil organic matter accumulation and degradation is a function of the quality and quantity of inputs added to the soil. Peacock *et al.,* (2001) reported that the quality and quantity of organic inputs determines the microbial community structure. However, the effect of the organic amendments on nutrient availability depends on their ability to decompose and its nutrient composition (Singh and Jones, 1976; Reddy *et al*., 2005).

Peacock *et al*. (2001) reported that microbial biomass and diversity are influenced by the quantity and quality of organic inputs. It was described as both a source and sink of available nutrients for plants uptake which plays a critical role in nutrient transformation in terrestrial ecosystems (Singh *et al*., 1989). Generally, microbial biomass is an indicator for assessing soil quality and restoration in different vegetation types (Groffman *et al*., 2001). Therefore, ecosystem stability and fertility is directly related to soil microbial activity and biomass (Smith *et al*., 1993). In this study, we hypothesized that different amendments used in the control of nematode can modify, to varying extents, the soil microbial biomass carbon, nitrogen and phosphorus. We aimed to investigate: (i) the effects of different amendments on the soil microbial biomass carbon, nitrogen and phosphorus and (ii) to select the most sustainable management system that will promote microbial biomass sink in plantain orchard treated with nematode amendments.

MATERIALS AND METHODS

The experiment was established at the National Horticultural Research Institute experimental plot in

Ibadan, South West Nigeria, (7^0 30' and 3^0 54'E; in an altitude of 234m above sea level). The soil had a pH of 5.89 (H_2O) and texturally sandy with a composition of 790 g / kg sand, 80 g / kg silt and 130 g / kg clay. The treatments comprised three varieties of plantain (*Agbagba, Obino l'Ewai* and *Pita 14*) and five amendments to control nematode: carbofuran, dried neem leaves, poultry manure, *Glommus mosseae* and no amendment (control). The treatments were arranged in a Randomized Complete Block Design (RCBD) and replicated three times. The total land area was 110 m x 28.5 m (3,135 m^2) with 15 plots in each replicates and each measured 5.0 m x 7.5 m (37.5 m^2). Soil samples were taken annually at a depth of 0 – 15 cm from each plot with respect to treatments and assessed for microbial biomass C (MBC) using the fumigation-extraction method according to Vance *et al*., (1987). The microbial biomass N (MBN) was determined using the method of Brookes *et al*., (1985). The microbial biomass P (MBP) was determined using the fumigation-extraction method according to Brookes *et al*., (1982). Data were subjected to descriptive statistics and analysis of variance (ANOVA) using GLM procedure (SAS, 2002) and means were separated using least significant difference (LSD) at 5 % level of probability.

RESULTS

Microbial biomass carbon under the application of *Glomus mosseae* was higher at years 1 and 2 after planting. Concentration of microbial biomass carbon under the application of poultry manure and *Glomus mosseae* was similar at 1st year after planting; however, it was significantly higher than other treatments at 2nd year (Table1). The microbial biomass carbon under poultry manure at three years after planting was significantly higher than other treatments. The least was observed without nematode control methods at years 1, 2, and 3 after planting.

Microbial biomass nitrogen under the application of poultry manure was higher than other nematode control treatments at the 1st and 2nd years but similar to dried neem leaves at the third year after planting. The concentration of microbial biomass nitrogen under the application of *Glomus mosseae* at year one was significantly lower than other treatments. The least was observed under the application of carbofuran at second and third years after planting (Table 1).

Concentration of microbial biomass phosphorus under the application of poultry manure was significantly higher than other treatments at years 1, 2 and 3 (Table 1). Microbial biomass phosphorus under the application of *Glomus mosseae* was significantly lower than other treatments at the first year after planting. Microbial biomass phosphorus concentration under the applications of dried neem leaves, *Glomus mosseae* and control was comparable and they were significantly higher than carbofuran at two years after planting. Microbial biomass phosphorus concentration under the application of dried neem leaves, poultry manure and *Glomus mosseae* are similar at the third year after planting (Table 1).

Table 1. Effects of nematode control methods on microbial biomass carbon, nitrogen and phosphorus at different years after planting under field conditions

Nematode control methods	Years after planting								
	1	2	3	1	2	3	1	2	3
	MBC (mg/kg)			MBN (mg/kg)			MBP (mg/kg)		
Dried neem leaves	319.02	301.38	214.96	34.77	38.86	48.88	2.8	3.9	4.1
Poultry manure	327.06	309.44	258.31	40.95	44.40	53.07	5.4	6.4	7.2
Carbofuran'	283.44	265.49	167.36	31.29	27.62	29.00	2.0	3.9	4.7
Glomus mosseae	339.38	321.83	220.22	26.40	31.98	38.42	1.2	3.1	4.6
Control	267.12	249.47	130.73	33.35	26.88	9.65	2.9	4.4	6.0
$LSD_{0.05}$	2.70	0.43	0.63	0.93	0.89	0.81	0.6	1.6	1.0

$LSD_{0.05}$ – least significant difference at 5 % level of probability, MBC - Microbial biomass carbon, MBN - microbial biomass nitrogen, MBP - microbial biomass phosphorus

DISCUSSIONS

The increase observed in microbial biomass carbon under the application of *Glomus mosseae* (AMF) could be as a result of higher soil carbon storage as reported by Rillig *et al*. (2001) that arbuscular mycorrhiza fungi contribute to soil carbon pool by increasing the hyphal biomass in the soils and root of the host plant. Reduction in microbial biomass phosphorus with the application of *Glomus mosseae* signifies effective utilization of phosphorus. Arbuscular mycorrhizal fungi colonization enhances the uptake of relatively immobile soil ions (Marschner and Dell, 1994; Liu *et al*., 2000).

Soil microbial biomass is an important component in the cycling of nutrients in soils particularly when organic materials are used as amendments (Aoyama and Nozawa 1993). It can be used to characterize the microbiological status of soil (Nannipieri *et al*., 1990). The soil and its components determine the microbiological activities that are facilitated by the microorganism (Zhu *et al.,* 2003). Aoyama and Nozawa 1993 reported that variation in N mineralization and immobilization processes of different organic materials defines the microbial biomass N pattern.

Glomus mosseae treated plots having the highest amount of MBC after one year is in corroboration with the work of Rillig *et al.(*2001), which suggests that mycorrhiza fungi contribute to soil carbon storage due to the hyphal biomass in the soils and root.

The data showed higher microbial biomass nitrogen at one and two years respectively in poultry manure amended plot and in dried neem leaves amended plot at three years after planting. According to Ross and Tate (1993), crop residues can have a large effect on soil microbial biomass and activity, which in turn, affect the ability of soil to supply nutrients to plants through SOM turnover. It was also observed that the least amount of microbial biomass phosphorus was observed at the arbuscular mycorrhiza amended plot (Table 1) this signifies effective utilization of phosphorus. This in line with the report of (Marschner and Dell, 1994; Liu *et al*., 2000) that AM colonization enhances the uptake of relatively immobile soil ions and far more mobile nitrogen (N) ions, particularly under drought conditions (Tobar *et al*., 1994).

CONCLUSIONS

The organic amendments have higher potential to broaden or enhance microbial biomass. Therefore, the dual purpose served by organic amendments should be harnessed in order to attain sustainability especially in large scale production of plantain.

ABSTRACT

Lettuce (Lactuca sativa L.) is the most valuable salad vegetable in the world. However, its production is affected by biotic and abiotic stresses and Fusarium oxysporium is one of the biotic stresses affecting lettuce production. The study was therefore conducted to determine the biocontrol effect of Trichoderma longibrachiatum on Fusarium infection in lettuce. Two varieties of lettuce (Greatlake and Eden) were propagated using conventional and in-vitro techniques. Soils endemic with Fusarium oxysporum were inoculated with mycelial plugs of Trichoderma longibrachiatum at different positions before lettuce were grown on them. The control soils were not treated with T. longibrachiatum. Results revealed that lettuce grown on T. longibrachiatum-treated soil had reduced incidence and severity of F. oxysporum while the controls of Greatlake and Eden lettuce propagated conventionally had Fusarium incidence values of 100% and 79% respectively. The ability of T. longibrachiatum to reduce Fusarium infection in lettuce indicates its potentials in improving plant health for sustainable food security.

Key words: Biocontrol; Disease; Lettuce; Management; *Trichoderma*

INTRODUCTION

Lettuce (*Lactuca sativa* L.) is an annual leafy vegetable from the Compositae (Asteraceae) family (Romani *et al*., 2002). It is regarded as an important crop because it is the most consumed among the salad vegetables (Nicolle *et al*., 2003). Lettuce is a rich source of vitamins and minerals, recommended as a fiber rich diet because of its low calorie (Filgueira, 2008). In addition, lettuce contains appreciable amount of β-carotene and lutein capable of reducing risk of cancers, cataracts, heart diseases and stroke (USDA, 2004). *Lactuca* has also been reported to prevent chronic diseases and its seeds are used for the treatment of inflammation and asthma (Pavlou and Vakalounakis, 2005).

Inspite of the importance of lettuce, its production is hindered by biotic and abiotic stresses. Among the biotic stresses are fungi in which *Fusarium oxysporium* is one. *Fusarium oxysporium* is the major cause of *Fusarium* wilt in vegetables. It is an important disease of lettuce all over the world causing yield losses ranging between 20 and 70% depending on cultivar susceptibility, management practices and the prevailing environmental conditions (Pasquali *et al*., 2007). Symptoms induced by *F. oxysporium* in lettuce include chlorosis and/or necrosis of older leaves, stunting and plant death before maturity (Scott *et al*., 2010). One of the management strategies of *Fusarium* infection is the use of fungi as biocontrol agents of the disease. *Trichoderma* spp. is a fungus which has the ability to antagonize the growth of disease-causing fungi by secreting enzymes which degrade the cell walls of other fungus (Kawalekar, 2013). The objective of this study is to determine the biocontrol properties of *Trichoderma longibrachiatum* on the incidence and severity of *F. oxysporium* in lettuce.

MATERIALS AND METHODS

Seeds of lettuce; Greatlake and Eden were obtained from National Horticultural Research Institute sub-station at Kano State. The seeds were packaged in sealed water-proof sachets until when needed.

Trichoderma longibrachiatum was obtained from the International Institute of Tropical Agriculture (IITA)-Bioscience Center, Ibadan. The isolate was maintained on Potato Dextrose Agar (PDA) and kept in the refrigerator at 4 ^oC until when required. *Fusarium oxysporum* was isolated from the rhizosphere of lettuce plant according to the procedure of Barakate *et al*. (2002). One gramme of soil sample obtained from the rhizosphere of lettuce was transferred into a test tube and 9 ml of distilled water added. Serial dilution was carried out until 10^{-6} dilution was obtained and aliquots of 1ml from the dilution were inoculated on PDA. The inoculation was done in duplicates and the plates incubated at 25 ^oC for 72 hrs after which the plates were examined for fungal growth. Pure cultures of *Fusarium oxysporum* were obtained from the mixed cultures produced after incubation. *Fusarium oxysporum* was maintained in the laboratory by periodic transfer onto slants on PDA and kept in the refrigerator at 4 °C until when required. Identification of *Fusarium oxysporum* was carried out using morphological and microscopic characteristics.

Biocontrol of *F. oxysporum* by *T. longibrachiatum* was carried out on the field. The experiment was divided into two groups. The first group was carried out by propagating lettuce on Murashige and Skoog (MS) medium. The micropropagated seedlings were moved to the acclimatization chamber and later transplanted on the field. During transplanting, a 10 mm cork borer was used to transfer mycelial plugs from actively growing margins of *T. longibrachiatum* on PDA into the soil and treatments were carried out as follows; (i) seedlings and *T. longibrachiatum* in the same 3 cm deep hole (T1), (ii) seedlings in 3 cm deep hole with *T. longibrachiatum* placed 3 cm below the seedlings (T2), (iii) seedlings in 3 cm deep hole with *T. longibrachiatum* placed on one side of the seedlings (T3), (iv) seedlings in 3cm deep hole with *T. longibrachiatum* placed 3 cm on both sides of the seedlings (T4), (v) seedlings in 3 cm deep hole without *T. longibrachiatum* (control). For the second group of experiment lettuce seeds were sown directly on the field and the same *T. longibrachiatum* treatments above were applied. Natural infection was allowed to set in as the field used was known to be endemic with *F. oxysporum* infection. The effects of the treatments were observed on disease incidence and severity of *F. oxysporum*.

RESULTS AND DISCUSSION

The incidence of *F. oxysporum* on the *in-vitro* propagated Greatlake lettuce revealed that 80% of the control plants were infected with the fungus. The susceptibility of the *T. longibrachiatum*-treated plants ranged from 25% to 42.85%. One hundred percent (100%) of the control plants of the conventionally propagated Greatlake lettuce were infected with *F. oxysporum* while the susceptibility of the *T. longibrachiatum*-treated plants ranged from 33.33% to 75% (Fig. 1a).

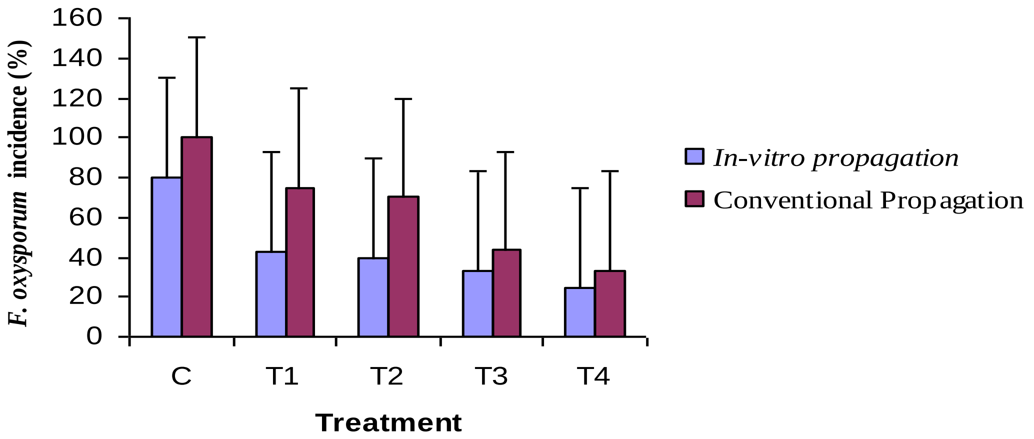

Figure 1a. Incidence of *Fusarium oxysporum* in Greatlake lettuce

The severity of the *in-vitro* propagated Greatlake lettuce to *F. oxysporum* revealed that the control had the highest severity score of 4. Treatments T3 and T4 were mildly infected while T1 and T2 were moderately infected by the fungus. The control plants of the conventionally propagated plants were severely infected by the fungus, very few survived the infection and the severity score was 5. The *T. longibrachiatum*-treated plants were not severely infected by the fungus, the severity scores tended towards moderate infection (Fig. 1b, Plate 1). This could be due to the ability of *T. longibrachiatum* to colonize the rhizosphere and utilize nutrients more than *F. oxysporum* (i.e competition). Among others, *T. longibrachiatum* may improve mineral uptake efficiency, increase resistance to abiotic stresses and exhibit adverse effect towards deleterious microorganisms or induce systemic resistance (ISR) in plants (Harman *et al*., 2004).

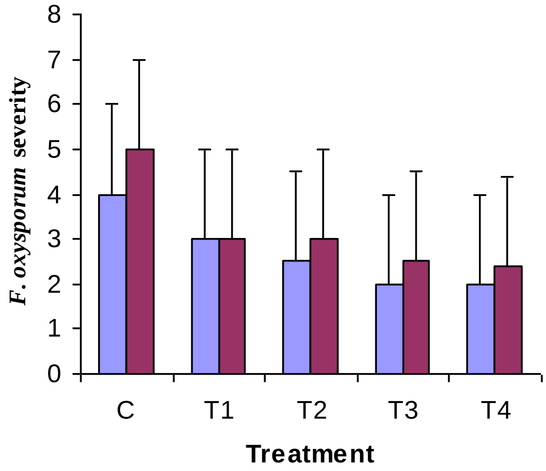

Figure 1b. Severity of *Fusarium oxysporum* in Greatlake lettuce

C- control; T1- seedling and *Trichoderma longibrachiatum* in the same 3cm deep hole; T2- seedling in 3cm deep hole with *Trichoderma* put 3cm below the seedlings; T3- seedling in 3cm deep hole with *Trichoderma longibrachiatum* placed on one side of the seedlings; T4- seedling in 3cm deep hole with *Trichoderma longibrachiatum* placed on both sides of the seedlings.

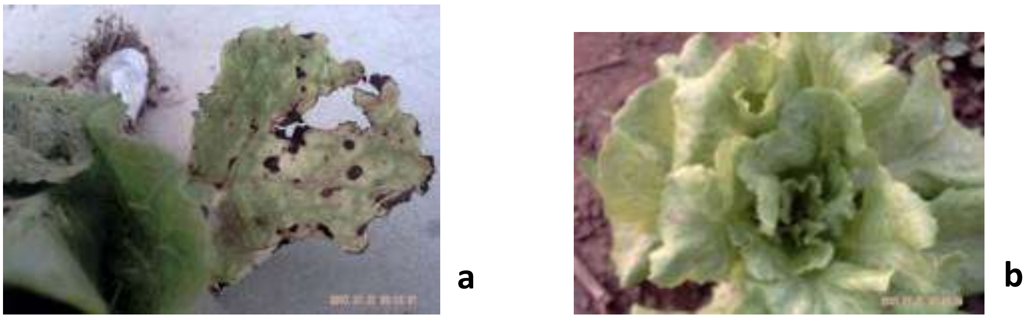

Plate 1. Conventionally propagated Greatlake lettuce (a) Control showing necrotic lesions and yellowing of leaves after infection with *Fusarium oxysporum* (b) *Trichoderma*-treated lettuce

The incidence of *F. oxysporum* in the micro-propagated Eden lettuce was very low in T4 with a mean value of 20% while those of the other *T. longibrachiatum*-treated plants were within the range of 38% to 50%. The incidence of the control of the conventionally propagated Eden lettuce was 79%, meanwhile, the fungal incidence of the *T. longibrachiatum*-treated plants was lower with T4 having the least value of 28% while those of T1, T2 and T3 were 44%, 55% and 42% respectively (Fig. 2a).

The severity of *F. oxysporum* on the *in-vitro* propagated plants was high in the control plants with a score of 4 while those of the *T. longibrachiatum*-treated plants had mean scores that ranged from 2 to 3. The severity score obtained from the control of the conventionally propagated plants was 4.5 while scores that ranged between 2 and 3.33 were recorded for the *T. longibrachiatum*-treated plants (Fig. 2b). The reason for this is the ability of *T. longibrachiatum* to grow faster than *F. oxysporum,* thereby occupying available space and utilizing available nutrients. This is in conformity with the report of Siameto *et al*. (2010) which stated that *T. harzianum* inhibited the growth of the target organisms through its ability to grow much faster than the pathogenic fungi thus competing efficiently for space and nutrients.

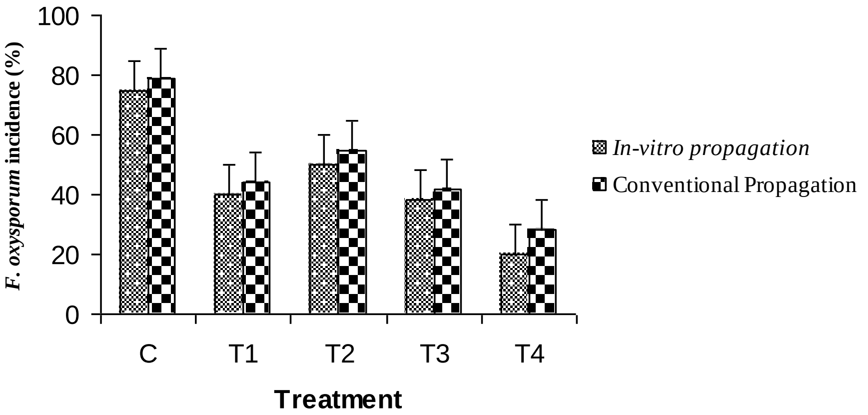

Figure 2a. Incidence of *Fusarium oxysporum* inEden lettuce

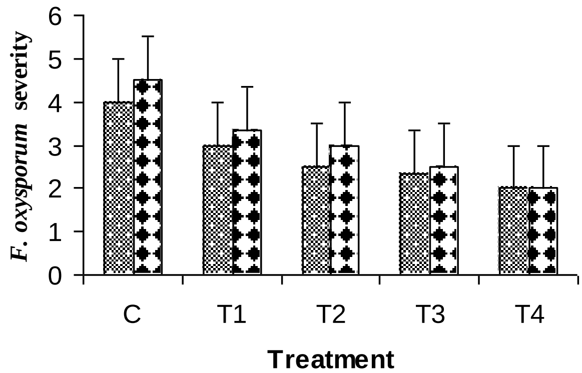

Figure 2b. Severity of *Fusarium oxysporum* in Eden lettuce

C- control; T1- seedling and *Trichoderma* in the same 3cm deep hole; T2- seedling in 3cm deep hole with *Trichoderma* put 3cm below the seedlings; T3- seedling in 3cm deep hole with *Trichoderma* put 3cm below the seedlings and in other 3cm hole on one side of the seedlings; T4- seedling in 3cm deep hole with *Trichoderma* placed in hole 3cm below and 3cm on both sides of the seedlings.

CONCLUSION

The use of plant growth-promoting fungi as biocontrol agents is promising in agricultural setting as they improve plant health with no adverse effect on the environment and the consumers at large. The use of *Trichoderma* spp. should be encouraged for use by farmers to enhance plant health and increase food security.

ABSTRACT

Kola nut is an important cash crop in Nigeria and some other African countries. It is a major source of livelihood to many, most especially, in the south western part of Nigeria. However, Balanogastris kolae infestation and damage has been a major challenge to kola nut while in storage. Several measures have been employed by farmers, particularly, the use of synthetic chemicals which have detrimental effects on man and the environment. In Nigeria, several studies have been conducted to investigate the potentials of some botanicals against B. kolae using bioassays and storage trials. Interestingly, all the plant samples tested were found effective against kola nut weevil's infestation. It was observed that as the concentrations of the plant samples (crude extracts and powders) increased, the mortality of adult B. kolae increased with increase in time of exposure. Therefore, any of the plant samples used in these researches can be explored as biopesticides against B. kolae. Future research should focus on determination of active components in candidate extracts and bioassay of those compounds against the kola weevil.

INTRODUCTION

Kola nut is a traditional plant belonging to the family *Sterculiaceae*. There are about 125 species of trees in this family native to the tropical rainforests of Africa. C*ola nitida* and *C. acuminata* are the two species that are very common most especially among the Yoruba tribe of Southwestern Nigeria (Odebunmi *et al*., 2009). *C. nitida* (Vent) Schott and Endl can be easily differentiated from *C. acuminata* (P. Beauv) Schott and Endl as it has two cotyledons with varieties of colour which are red, pink and white. *C. acuminata* on the other hand has three to six cotyledons. Farmers cultivate *C. nitida* more than *C. acuminata* because of its higher economic importance (Adeyeye *et al.,* 1994).

The nut has varying degrees of importance to the three major Nigerian ethnic groups, the Hausa, Igbo and Yoruba. Kola nuts are used as stimulants because they contain caffeine and theobromine. They are equally used in the production of beverages and pharmaceutical products due to these alkaloids and other phytocompounds they possess. Kola nuts also find application in the textile industry as they possess tannins and they are also used in production of wines, liquid soap, soft drinks and feed formulation, among other uses (Azeez, 2015; Ndagi *et al*., 2012).

However, Nigeria has witnessed a downward trend in kola nut production due to numerous factors such as the trees not producing fruits or very low yield due to self-and-cross incompatibility among trees, partial and total sterility, inefficient natural pollination, old age, field and storage pests, and diseases (Ndagi *et al*., 2012; Mokwunye *et al*., 2017). Kola nut weevils, *Balanogastris kolae* and *Sorphrorhinus* spp. are the two most important field-to-store pest of kola nut (Asogwa *et al*., 2015, Azeez 2015).

ECONOMIC IMPORTANCE OF *BALANOGASTRIS KOLAE*

The *a*dult kola weevil, *Balanogastris kolae* (Desbrochers), a member of the *Curculionidae* family is the most common pest of kola nut. They are identified as field-to-store pests of kola because their infestation starts from the field and continues till storage, thereby causing huge losses to stored nuts (Azeez, 2015). They are usually dark brown to grey in colour and 0.3 - 0.4 cm long and 0.15 - 0.2 cm wide.

The female oviposit either on the nuts or inside it to about 1cm deep through wounds or holes created by other insects or through cracks on the husk that occurred when the follicles dehisce before harvest or during processing. Larva feeds extensively on kola nut thereby reducing it to yellowish brown powdery mass (Popoola *et al*., 2020). Kola weevils have a rostrum which they use to bore into the nut and feed on internal content. Larvae feed on the kola nut cotyledon and develop inside the nuts. The undetected infestation of kola nuts in storage by these weevils results in considerable high losses, which sometimes can be as high as about 60% of the total production in a year (Asogwa *et al*., 2015).

MANAGEMENT OF KOLA WEEVIL WITH INSECTICIDES

In order to prevent kola nuts in storage from the attack of kola weevils and other pests, farmers and traders use various types of pesticides which are very effective in protecting the products (Lale, 2002). These chemical pesticides include lindane, cypermethrin and phostoxin that are banned due to their detrimental effects in the environment. Some of these insecticides are systemic in nature and usually they do not easily biodegrade after application, they remain as residues in the environment. Aikpokpodion *et al* (2013) reported that kola nuts obtained from selected markets in southwestern Nigeria contained some levels of residues of chlordane and endosulfan. The effects of exposure to pesticides on human includes: development of different types of cancers as well as the risk of immunotoxic, neurotoxic and adverse reproductive effects. They also cause an increased incidence of psychiatric and dermatologic conditions (Alavanja *et al*., 2004; Sanborn *et al*., 2004). Due to the detrimental effects of synthetic pesticides, they are seriously discouraged from being used for the control of storage insect pests and this necessitates the search for alternative sources for the containment of storage insect pests. Several plant extracts, volatile oils and compounds have been reported as effective biopesticides against many stored product pests (Aikpokpodion *et al*., 2013; Asogwa *et* al., 2015; Adewole and Alabi, 2017; Noudegbessi *et al*., 2021).

Investigations on the efficacies of insecticidal plants for control of weevils on storage kola nut in Nigeria, has received much attention. The different results obtained from the studies indicate that there is a potential to be valued after several years of research from the various botanicals. To achieve this, an analytical synthesis of the results and a reframing of the researches are needed to optimize the practical use of plants that have already proved their effectiveness. Therefore, this review on the potential of the plants species for the control of *B. kolae* summarizes the researches undertaken since early 2000 till 2020.

PLANT SPECIES WITH INSECTICIDAL POTENTIAL TO CONTROL *B. KOLAE*

The use of plant material for the preservation of storage products is considered as a promising alternative to synthetic insecticides (Akunne *et al*., 2018). In Nigeria, several studies have been carried out on the effects of plants with insecticidal potential to control *Balanogastris kolae* infestation (Table 1). Extensive studies were conducted on some plant species from different families through bioassays and storage trials on *B. kolae*. Plants with biopesticides ability were found in 18 plant families. The plants with pesticidal properties were distributed among the following growth habits; tree (*Senna alata, Cedrela odorata, Alstonia boonei, Azadiracta indica, Hura crepitans*), shrubs (*Jatropha curcas*, *Vernonia amygdalina*) and herbs (*Hyptis sauveolens, Musa paradisiaca*). All categories of plants produce secondary plant metabolites that play important roles in the ecosystem and one of such is pesticidal attributes.

POTENTIAL OF BOTANICALS TO CONTROL *B. KOLAE*

The insecticidal ability of the plants tested against *B. kolae* can be divided into bioassays and storage trials. In all the studies conducted, crude extracts (aqueous and ethanolic extracts) and powdered plant materials were used. They were found to be effective against *Balanogastris kolae*, though they were all dose dependent. However, Azeez 2015 reported that ethanolic plant extracts of *Lycopersicon esculentum, Hyptis suaveolens, Cymbopogon citratus, Loranthus braunii, Alstonia boonei and Sarcocephalus latifolius* caused 100% mortality of the weevils within 20 minutes of exposure whereas the aqueous extracts achieved 10% or none for the same period. Similar trend was observed by Ugwu *et al*., 2019 in which at 100% concentrations of *Azadiracta indica*, *Piper guineense* and *Afframomum melegueta*, caused 100% mortality of the adult *Balanogastris kolae*.

Table 1. Plants materials used experimentally for the control of *Balanogastris kolae* from early 2000 to 2020 in Nigeria

Plant species tested	Family name	Common name	Parts used	Mode of action	Reference
Senna alata	Fabaceae	Candle stick	Leaf	Stomach Poisoning	Ifebueme *et al.*,2020
Hura crepitans	Euphorbiaceae	Sand box tree	Leaf	Stomach Poisoning	Ifebueme *et al.*,2020
Calophyllum inophyllum	Calophyllaceae	Alexandra laurel tree	Leaf	Stomach Poisoning	Ifebueme et al.,2020
Nicotiana tabacum	*Solanaceae*	Tobacco	Leaf	Stomach Poisoning	Asogwa et al., 2015
Vernonia amygdalina	*Asteraceae*	Bitter leaf	Leaf	Stomach Poisoning	Asogwa et al., 2015
Eucalyptus camaldulensis	Myrtaceae	Red river gum	Leaf	Stomach Poisoning	Asogwa et al., 2015
Hyptis sauvolens	Lamiaceae	Pignut	Leaf	Stomach Poisoning / Contact toxicity	Asogwa et al., 2015 and Azeez 2015
Musa paradisiaca .	Musaceae	Banana	Stem	Stomach Poisoning	Asogwa et al., 2015
Cymbopogon citratus	Poaceae	Lemon grass	Leaf	Stomach Poisoning / Contact toxicity	Asogwa et al., 2015 and Azeez 2015
Lantana camara	Verbanaceae		Leaf	Stomach Poisoning	Asogwa et al., 2015
Tetrapleura tetraptera	*Mimosaceae*	Aidan	Fruit	Contact toxicity	Anikwe et al 2005
Azadirachta indica	*Meliaceae*	Neem	stem bark	Stomach Poisoning	Asogwa et al., 2009 and Ugwu et al., 2019
Cedrela odorata	*Meliaceae*	Spanish cedar	stem bark	Stomach Poisoning	Asogwa et al., 2009
Chrysophyllum albidum	*Sapotaceae*	White star apple	stem bark	Stomach Poisoning	Asogwa et al., 2009
Khaya senegalensis	*Meliaceae*	African mahogany	stem bark	Stomach Poisoning	Asogwa et al., 2009
Chromolaena odorata	*Asteraceae*	Siam weed	Leaf	Stomach Poisoning	Asogwa et al., 2009
Lycopersicon esculentum or *Lycopersicon solanum*	*Solanaceae*	Tomato	Leaf	Contact toxicity	Azeez 2015
Loranthus braunii	*Loranthaceae*	Mistletoes	Leaf	Contact toxicity	Azeez 2015

ISSN: 2814-0508

Alstonia boonei	*Apocynaceae*	Stool wood	Leaf	Contact toxicity	Azeez 2015
Sarcocephalus latifolius	*Rubiaceae*	*African peach*	Leaf and bark	Contact toxicity	Azeez 2015
Derris elliptica	*Fabaceae*	Poison vine	Root	Contact toxicity	Akunne et al., 2018
Jatropha curcas	*Euphorbiaceae*	Barbados nut	Seed	Contact Toxicity/stomach poisoning	Ugwu et al., 2019
Piper guineense	*Piperaceae*	Black pepper	Seed	Contact Toxicity/stomach poisoning	Ugwu et al., 2019
Afframomum melegueta.	*Zingiberaceae*	Alligator pepper	Seed	Contact Toxicity/stomach poisoning	Ugwu et al., 2019

The powdered root and fruit of *Derris elliptica* and *Tetrapleural tetraptera*, respectively were investigated on the adult mortality of the kola nut weevil. It was discovered that at higher doses, the two plant samples were efficacious against *Balanogastris kolae* (Akunne *et al*., 2018 and Anikwe *et al*., 2005). Ethanolic plant extracts of *Senna alata*, *Hura crepitans* and *Calophyllum inophyllum* at various concentrations recorded a significantly lower adult emergence from week five to nine after treatment applications compared with the untreated, although storage of kola nut with 1.5 g of *C. iInophyllum* was found to be more potent.

Moreover, from storage trial experiments carried out by Asogwa *et al*., 2009 and Asogwa *et al*., 2015 in which ethanolic and aqueous plant samples of *Azadirachta indica* (stem bark), *Cedrela odorata* (stem bark), *Chrysophyllum albidum* (stem bark), *Khaya* spp. (stem bark), *Chromolaena odorata* (leaf) and leaf samples of Nicotiana tabacum L., *Vernonia amygdalina* Delile, *Eucalyptus camaldulensis* Dehnh, *Hyptis sauvolens* Poit, *Cymbopogon citratus* Stapf, *Lantana camara* L. and the base trunk of *Musa paradisiaca* L. ,respectively were evaluated against kola nut weevil. The emergence of adult *B. kolae* decreased with increasing concentrations of the various extracts.

CORRELATION BETWEEN INSECTICIDAL PROPERTIES OF BOTANICALS AND THEIR PHYTOCONSTITUENTS

Secondary metabolites are synthesized by plants and they function as defense mechanisms against damage cause by herbivores (Ifebueme *et al*., 2020). These synthesized secondary metabolites influence the behavior of growth or survival of these herbivores (Duke *et al*. 2010). From Table 2 below, all the plants used have the major phytochemicals such as saponins, flavonoids, tannins, alkaloids, phenols, and cardiac glycoside. These are known to have activity against pathogens and therefore aid the insecticidal activities of botanicals (Ghosh *et al*., 2010). Saponins generally have a wide range of biological activities which may have roles in plant defense. This is usually attributed to the fact that most of them consist of a hydrophobic triterpene or sterol backbone and a hydrophilic carbohydrate chain (amphipathicity), thus permeating plasma membrane where they form complex with sterols and cause the formation of pores in order to exert their cytotoxic effect (Armah *et al*. 1999 and Mugford *et al*., 2013). Also, flavonoids are very important in plant resistance to pathogens as its compounds are transported to the site of infection and triggers hypersensitivity reaction, which consequently causes cell damage or death (Mierziak *et al*., 2014). Flavonoids can also prevent insects from laying eggs (War *et al*., 2012).

CONCLUSION AND RECOMMENDATION

Kola nut is a major cash crop grown in Nigeria for its economic, social and traditional uses. It is very important to preserve these nuts from *Balanogastris kolae* infestation preferably by using any of the botanicals listed in this review since they showed insecticidal potentials against the insect. Further works have to be done to identify and characterize the active ingredients present in these botanicals.

ABSTRACT

The study was conducted at the Entomology Laboratory of CRIN to evaluate the population trend of Balanogastris kolae in kolanut treated with powders extracts of Rice Husk and Melon Shell (RHP and MSP), under tropical ambient conditions. The test insect was reared in basket lined with black polyethene sheet on kolanut obtained from local market. RHP and MSP at four levels of 4,8,12 and 16g/kg were applied on healthy kolanut in basket lined with black polyethene sheet. Five pairs ((♀&♂) of B. kolae were introduced to each treatment. An untreated control and standard control treated with 8g of Phostoxin/kg of healthy kolanut was set up. Population trend of emerging weevil was monitored by taking live and dead counts on weekly basis for a period of 4 months. The experiment was arranged in a Completely Randomized Design in three replicates. The RHP treatment recorded significant mortality of 33.33% of B. kolae at high levels of application (16g/kg of kolant), 48 hours after application. Both treatment reduced F_1 progeny population of B. kolae as against the untreated control. Treated kolanut showed considerably low percentage weight loss unlike the untreatment control. Percentage weight loss due to insect infestation and weight loss due to mould growth as secondary infection were positively correlated and both negatively correlated to adult mortality rate. As an alternative for food safety, from this study, the results obtained indicated that higher dosage of RHP and MSP can be used to reduce weevil infestation in kolanut.

Key words: *Balanogastris kolae,* Rice Husk Powder, Melon Shell Powder, population, kolanut

INTRODUCTION

Cola is a tropical plant belonging to the genus of the family Malvaceae and Subfamily Sterculioideae. It is indigenous to Tropical Africa with great diversity in West Africa (Opeke, 1982; 1992; 2005) of which two species *Cola nitida* and *Cola acuminata* are of economic importance. West African countries like Nigeria, Ghana, and Ivory Coast are major producers of kolanuts with Nigeria accounting for about 70% of the total world production of kola nuts (Oluokun and Oladokun, 1999). About 90% of the kola nuts produced in Nigeria is locally consumed and the remaining 10% exported to other parts of Africa especially neighboring countries in West Africa (Oluokun and Oladokun, 1999; Okunade, 2003). The *C. nitida* and *C. acuminata* commonly referred to as kolanuts are consumed raw as masticatory because of their stimulating effects. Their nuts are important raw materials in the pharmaceutical and confectionery industry where the essential oils such as theobromine, caffeine and kolatine are used (Ogutuga, 1975, Akinbode, 1982). It is also a source of colorants for dyeing in textiles and threads due to the presence of tannin. Kola nut plays significant role in the tradition and spiritual practice of many West African ethnic groups (Esther *et al*., 2010).

With the high values attached to kolanut and high demand in Africa, its production keeps declining due to a number of factors amongst which are the insect pests' infestations from field to store. The attack of weevils of different species in kolanut production which is usually from field-to-store is a notable challenge. *Balanogastris kolae* and *Sophrorhinus spp.* are predominant damaging insect pests of economic importance which often result to about 100% loss without proper control in kolanut storage (Asogwa *et al*.., 2008). Weevil infestation also predisposes the nuts to fungal attack thus reducing the market value and causing subsequent destruction of the nuts. The major problem reported in kola nut trading business was mainly insect attack, causing up to 53.33% damage (Esther *et al*.., 2010).

However, kolanuts are usually consumed raw, thus the choice of weevil control is of great concern. Kolanut is often stored for as long as a year or two by traders that prefers the choice of synthetic pesticides to reduce weevil damage and reduce economic losses. Olorunmota *et al.,* (2021), in a survey of methods of kolanut preservation in 3 Southwestern States of Nigeria reported that only 2.5% of respondents in each state adopted the use of botanicals while over 90% used insecticides, which have the potentials to leave residues in the nuts. Several authors have reported the presence of pesticide residues in various foods, vegetables, soils, sediments and diverse environment. Unlike some produce that pass through primary processing before consumption kolanut does not, there is need therefore to source for safer alternatives with minimal or no human and environmental health hazards.

Many authors have reported the efficacy of plant materials in controlling store product insect pests. These include but not limited to the powders, essential oils and aqueous extracts of *Azadiracta indica, Curcuma longa, Tetrapleura tetreptera, Cassia nigricans* and *Capsicum spp*. *Piper ginnensis*and *Nicotiana spp* have been shown to be effective against bruchids, curulionids and the *Tribolium castaneum.* Seeds of *Azadiracta indica* and *Dennettia tripala* and the fruits of *Piper guinenses* have pesticidal and behaviour modifying properties against various pests of stored products (Agbakwuru *et al.,* 1978; Ivbijaro and Agbaje 1986; Lale, 1992).

MATERIALS AND METHODS

This study was conducted in the Entomology Laboratory of the Cocoa Research Institute of Nigeria (CRIN), Ibadan, Nigeria located at an approximate geographical coordinate of 07°10'N, 03° 52'E, 122 m ASL and the Tropical Ambient Laboratory conditions during the period of study were 28 ± 4°C temperatures and 68 ± 10% relative humidity.

Source of kolanut Used for the Experiment

Freshly harvested "unskinned" kolanuts (*Cola nitida*) were bought from local markets in Ogun state of Nigeria. The purchased nuts were kept in woven basket for a period of five days during which, they were sprinkled with water and turned to facilitate decay and easy removal of the testa. After the removal of the testa, the nuts were rinsed in clean water, drained and spread on the laboratory table to gradually drain out the water absorbed during the curing process. The nuts were sorted into healthy and infested nuts. All nuts with entry and or exit holes, feeding points and any developmental stage of insects were removed while the remaining nut were further cured in baskets lined with banana leaves and covered with same for 3 days to achieve sweating of the nuts and reduce the water content of the nuts. The nuts were removed and sorted again and the banana leaves were changed for curing the nuts for another 3days. On the third day, the kolanuts were checked and all damaged nuts were removed while the remaining healthy nuts were used for the experiment.

Culturing of Insect

The kola weevil, *Balanogastris kolae* used for the experiment was obtained from already infested nuts purchased from the market. The nuts were kept in a polyethene bag and checked at three days' intervals to collect new emergent. Also, the nuts with entry/exit holes oviposition holes and feeding points which were sorted out during the curing process were kept in another basket lined with black polyethene sheet and checked weekly for weevil emergent. The cultures were maintained in the laboratory and the daily emerging adult weevils were used for the bio-assay.

Collection and Preparation of the Powders

Rice husks and melon shell used for the experiment were obtained from Bodija Local Market in Ibadan. Each material was air-dried and blended into fine powder, allowed to cool and stored in an air-tight container. The conventional Aluminium phosphide tablet, used by kolanut traders was purchased from an agrochemical store to set up a standard control.

Experimental Design

The experiment was laid out in a Completely Randomized Design (CRD) and each treatment
was applied at four levels of: 4.0, 8.0, 12.0 and 16.0 g per kg of healthy kolanut in a black polyethene sheet kept in a woven basket. A standard control with 0.8g of Aluminium phosphide per kilogram of kolanut and no-treatment control were set up. The treatments and the two controls were replicated thrice. Each powdered material was well mixed with the kolanut for even distribution. Five pairs (♀&♂) of new emergent of *Balanogastris kolae* from the cultures in the laboratory were introduced into each 0.5kg kolanut in a nylon kept in woven basket. Adult mortality of the weevils was counted and represented in percentages, at 48hrs after weevil introduction while the remaining weevils were removed. The nuts were checked on weekly basis for adult emergence and the live and dead counts of the emerged weevils were recorded for a period of four months. The powdered material was removed as soon as it was seen to have absorbed moisture from the nuts and the nuts exposed for few hours to dry before being tied again. At the end of the experiment, kolanuts with mould growth were removed and weighed and the kolanut without entry/exit hole and mould growth were considered as healthy nuts and were also weighed. Weight loss

was computed by deducting the final weight from the initial weight of 500g.

Data Analysis

Data collected were subjected to analysis of variance (ANOVA) using SAS version 9.1 software package and Duncan's Multiple Range Test (DMRT) was used to separate the means at 5% probability level.

Percentage Mortality and percentage weight loss were calculated as follows:

$$\text{Percentage Mortality} = \frac{\text{No. of dead weevil}}{\text{No. of weevils introduced}} \times 100(\%)$$

$$\text{Percentage Weight loss} = \frac{(W_1 - W_2)}{(W_2)} \times 100(\%);$$ where W_1 is initial weight and W_2, the final weight

RESULTS

Mortality of the introduced weevil in the experiment as seen in Table 1 showed significantly low (P ≤ .05) toxicity on *B. kolae* in both treatment and the control, unlike the standard control. The powders had significantly low toxicity when compared with the conventional Phostoxin used by kolanut traders. The MSP treatment at all levels of application recorded zero mortality just as the no treatment control, while the RHP treatments though at 4.0 and 8.0 level of application recorded zero kill also, but at 12.0 and 16.0 recorded 3.33 and 13.33 kill of the insect. The standard control of Phostoxin recorded significantly higher (P ≤ .05) mortality (90.00) of *B. kolae*.

Table 1. Percentage mortality of *B. kolae* in the powders

Conc.(gkg^{-1})	Adult mortality	
	RHP	MSP
0	0.00c	0.00c
4.0	0.00c	0.00c
8.0	0.00c	0.00c
12.0	3.33c	0.00c
16.0	13.33b	0.00c
Standard	90.00a	90.00a

Means with the same subscripts are not significantly different at (P ≤ .05) using DMRT, RHP- Rice Husk Powder, MSP- Melon Shell Powder

Table 2 shows the population growth of *B. kolae* in the treatments. *B. kolae* in the standard control had significantly low (P ≤ .05) population growth when compared with the treatments. From the total adult emergent the no-treatment control recorded significantly higher value of 46.33 as against the treatments at all levels of application. RHP and MSP treatment at lower application rate of 4.0g/kg recorded 32.67 and 25.99 and at highest application rate of 16.0g/kg recorded 15.66 and 17.66 respectively However, the standard control treatment had significantly (P ≤ .05) low population growth of 0.66 compared to the treatments.

Table 2. Population growth of *B. kolae* in the powders

Conc(gkg$^{-1)}$	Dead		Live		Total Emergent	
	RHP	MSP	RHP	MSP	RHP	MSP
0	0.00f	0.00f	46.33a	46.33a	46.33a	46.33a
4.0	13.00a	9.00bc	19.67bc	16.00bcd	32.67b	25.99cd
8.0	11.00ab	11.00ab	21.33b	15.66cd	32.33b	26.99c
12.0	4.33e	8.67bc	14.66cd	13.33d	18.99e	22.00d
16.0	2.33de	6.00dc	13.33d	11.67d	15.66fg	17.66ef
Standard	0.33f	0.33f	0.33e	0.33e	0.66h	0.66h

Means with the same subscripts are not significantly different at (P ≤ .05) using DMRT
RHP- Rice husk powder, MSP- Melon shell powder

Mean dead count of adult *B. kolae* in both powders is significantly different (P ≤ .05) from the no - treatment control and the standard control which recorded 0.00 and 0.33 respectively. At lower application rate of 4.0g/kg mean dead count in RHP and MSP treatments were 13.00 and 9.00 while at the higher rate of 16.0g/kg they recorded 2.33 and 6.0 respectively. The weight of mouldy nuts was significantly higher in the no- treatment control than the treatments (Table 3). Mouldy nuts accounted for 116.67g in the no treatment control while the MSP treatment recorded 36.67g at a lower application rate of 4.0g/kg to as low as 16.67g in the high application rates of 8.0 12.0 and 16.0g/kg that is not significantly different from the standard control. The RHP treatment also recorded significantly low weight of mouldy nuts at all levels of application as against the no treatment control.

Percentage weight loss in the treatments at all levels differs significantly from untreated control. While the untreated control lost up to 59.33% weight, the MSP treated kolanut lost between 17.33 to 28.67% and RHP treated kolanut lost between 22.13 to 42.67%.

Table 3: **Mean Percentage weight loss in treated kolanut**

Conc (gkg$^{-1)}$	**Weight of Mouldy nuts**		**% Weight loss**	
	RHP	MSP	RHP	MSP
0	116.67a	116.67a	59.33a	59.33a
4.0	58.33b	36.67b	42.67b	28.67bcd
8.0	11.33b	16.67b	22.13d	38.00bc
12.0	12.67b	16.67b	22.60cd	20.67d
16.0	54.67b	16.67b	30.67bcd	17.33d
Standard	13.33b	13.33b	16.00d	16.00d

Percentage adult mortality was negatively correlated to weight of mouldy nuts and percentage weight loss. There was however a positive correlation between weight of mouldy nuts and percentage weight loss in treated kolanut (Table 4).

Table 4. Correlation between Adult Mortality, Mould weight and Weight loss

	% Mortality	Mould weight	Weight loss
% Mortality	1.00	- 0.15	- 0.30
		0.42	0.11
Mould weight	- 0.15	1.00	0.80
	0.42		< 0.0001
Weight loss	- 0.30	0.80	1.00
	0.11	< 0.0001	

DISCUSSION AND CONCLUSION

There was a relatively high percentage mortality recorded in the RHP treatments especially when compared with the no treatment control. This high mortality occurred at high level of application. It indicated that higher dosage is needed to achieve appreciable kill of the weevils. High level of efficacy at high level had been reported by many authors. Efficacy of powdered plant materials like *Eugenia aromatica, Aframomummelegueta*, wood ash against *Sitophilus zeamais*, *Rhizoperta dominica* and *Calosobruchus maculatus* at high concentrations were reported by different authors (Lajide *et al*., 1998: Olorunmota *et al*., 2021). In the present study the two powders induced significantly low F_1adult emergence of B. kolae in contrast to the no treatment control. The reduction in F_1 progeny emergence in the kolanut treated with RHP and MSP might be resulted from increased ovicidal and larvicidal properties of powders which agrees with the findings that leaf bark, seed powders, oil extracts of plants reduced oviposition rate and suppress progeny production in stored grains (Shaaya et al., 1997; Tunc *et al.,* 2000; Tapondjou *et al*.,2002). Ofuya (1990) and Tapondjou *et al*. (2002) have suggested that oviposition inhibition property of botanical powders on adult *C. maculatus* by weakening of adults in grains treated with plant powder made them laid fewer eggs and killed the larvae that hatched from eggs laid on grains. These two powders may hinder the movement of male weevil to locate the female weevil and cause reduced ovipostion. Blockage of the spiracles of the weevils by the powders may occur which will impair spiracle respiration and the subsequent death of the weevil (Law-Ogbomo and Enobakhare, 2007; Mulungu *et al*., 2007).

This oviposition inhibition effect on Sitophilus zeamais in maize grain treated with RHP and MSP was also reported by Olorunmota *et al.,* (2021), however, the ash of these two powders were said to be highly effective in inhibiting oviposition by the weevil.

The significantly low weight loss as a result of weevil infestation and mould growth on the treated kolanuts as contrast to the no-treatment control demonstrated that the powders at higher dose could serve as a cheap and safe alternative to the use of insecticides in kolanut storage. There is need for future research on the use of ash from these two waste farm products in controlling *Balanogastris kolae* in kolanut storage.

The fact that the powders killed relatively low weevil in contrast to phostoxin, which is synthetic does not negate the assertion that there should be check in its usage especially in kolanut which does not undergo any primary processing before consumption. The low adult emergence and reduced weight percentage weight loss, recorded in the powders as against the no treatment control is an encouragement for the production of organic kolanut, perhaps at increased rate of application and /or trials on some other bioactive plants materials that have volatile compounds with pungent smell that can serve as fumigants like Phoxtoxin.

ABSTRACT

Entomo-lethal effects of Fish Bean Plant, Tephrosia vogelii extracts were tested on the population of Eggplant Fruit and Shoot Borer (EFSB) infesting eggplant var. Solanum gilo in the field. The trial was conducted 2018 cropping seasons. The experiment was laid out in Randomized Complete Block Design (RCBD) with four replications. Six treatment levels of 9% v/v (T_9), 18% v/v (T_{18}), 27% v/v (T_{27}) of ethanol extracts of T. vogelii and 10% w/v (T_{10}), 15% w/v (T_{15}) and 20% w/v (T_{20}) of T. vogelii aqueous extracts, Cypermethrin and control were applied as treatments. Data were taken on percent shoot and fruit infestations, numbers of adult moth and larvae of L. orbonalis. Statistical analysis was by means of Analysis of variance using GenStat Software Programme 2010. Results of analyzed data showed that treatments were significantly ($P<0.05$) effective in controlling the infestation of EFSB on S. gilo when compared with the control. The treatments also varied significantly in their efficacy against the population of L. orbonalis adult moth and larvae at $P=0.05$. Amongst the T. vogelii extracts tested, T_{27} had the lowest percent fruit infestation (4.17%). Numbers of adult moth and larvae of L. orbonalis were also significantly reduced in all the treated plants compared to the control.

Key words: *Leucinodes orbonalis,* Eggplant, Damage, Infestation, *Tephrosia vogelii*

INTRODUCTION

There are many species of Eggplant; over 1000 species are well known and documented (Grubben and Denton, 2004). Eggplants are scientifically referred to as *Solanum Species* and they belong to the family, *Solanaceae* (Agoreyo *et al.,* 2012). They are grown all over the world. They are cultivated for food and medicine, and 25 species have been known to be most popular and domesticated in Nigeria (Bonsu *et al.,* 2002).

Eggplants has appreciable quantities of some phytochemical compounds especially saponins, phenols, flavonoids, tannins among others. They also serve as supplementary source of nutritional and medicinal requirements in our daily diets, especially in southeastern Nigeria. Consumption of Eggplant fruits are helpful in the prevention and treatment of several folklore ailments., it lowers the level of blood cholesterol, it plays effective role in blood pressure regulation, aids in weight reduction and it possess anti-haemorrhoidal and anti-glaucoma effects, the use of the roots and fruits as carminative and sedatives, and to treat coelic problems, leaf juice as a sedative to treat uterine complaints, an alcoholic extract of leaves as a sedative, anti-emetic and to treat tetanus after abortion (Ibiam, and Nwigwe, 2013; Doganlar *et al.,* 2002).

The economic importance of eggplants can never be overemphasized. Most rural and semi-urban farmers are dependent on the production of the fruits as means of livelihood and survival, economic empowerment and emancipation. In southeastern Nigeria, there is a daily demand for the fresh leaves and fruits of eggplants as most staple local delicacies are cooked with them. It is a fruit or vegetable crop of significant importance to the culture and tradition of the locals.

One of the greatest challenges facing the cultivation of eggplant is pest insects. Eggplant Fruit and Shoot Borer, *L. orbonalis* has been reported as the most significant and economic pest insect infesting the fruits and shoots of this crop (Uwalaka *et al,* 2018). The nature of damage of *L. orbonalis* is such that it renders the fruits unwholesome, reduces the nutritional qualities and shelf life, and exposes the shoots and fruits to secondary pests (Emeasor and Uwalaka, 2018). The time of infestation by *L. orbonalis* and timely application of effective control measures is very important in effective control of *L. orbonalis.*

This scientific study was focused on the evaluation and determination of most efficacious rate of application of aqueous and ethanol extracts of Fish Bean plant, and application frequency.

MATERIALS AND METHODS

The seeds of *S. gilo* were sourced from National Horticultural Research Institute (NIHORT) Mbato Outstation Okigwe, Imo State. Seedlings of *S. gilo* were nursed and transplanted to the experimental units at 6 weeks old. Fresh leaves of fish bean plant; *T. vogelii* leaves were harvested and dried at room temperature (20°C - 25°C) for 14 days, then ground to fine powder with a motorized blender. Aqueous extract of *T. vogelii* was formulated by mixing the powdered plant material with distilled water following the methods of Inades, (1996) and Sihwinarni, (1999). Three levels of the aqueous extract: 10% w/v, 15% w/v, and 20% w/v were made. Ethanol extract of *T. vogelii* was formulated by mixing 25 kg of ground freshly harvested leaves with 20 L of ethanol and 1 cup of detergent (Karlsson, 1995). Dilution was made to obtain; 9% v/v, 18% v/v and 27% v/v. Cypermethrin (10 E.C) was applied at manufacturer's recommended rate (Hamman *et al.,* 2012) and Control (no treatment application). Three application frequencies were adopted in this study; spraying once a week (1WK), once in two weeks (2WK) and once in three weeks (3WK).

The experimental design was 8 x 3 factorial experiments with 8 levels of botanical treatment and 3 levels of application frequency laid out in Randomized Complete Block Design (RCBD) with 3 replications. The plot size measured 2.25 m x 2.25 m and plant spacing was 0.75 m x 0.75 m which gave 16 stands of plant per plot. Data were taken on percent shoot and fruit infestations, numbers of adult moth and larvae of *L. orbonalis.* Statistical analysis was by means of Analysis of variance using GenStat Software Programme 2010.

RESULTS AND DISCUSSION

Figure 1 shows that treatments were effective in controlling the infestation of EFSB on *S. gilo* though significant variation ($P \leq 0.05$) existed amongst the treatments. The lowest percent fruit infestation, 2.04% was observed on plots treated with Cypermethrin (CYP) while the highest, 77.04% was observed at the control plot (C). However, CYP differed significantly ($P \leq 0.05$) from the other treatments in reducing fruit infestation of EFSB except 27% v/v *T. vogelii* ethanol extract (T_{27}) at which percent fruit infestation of 4.17% was observed. The percent mean infestation observed at the control treatment differed significantly from the other treatments ($P<0.05$). This finding corroborate the earlier report of Onekutu, (2011) that *L. orbonalis* infestation caused between 75%-90% yield reduction.

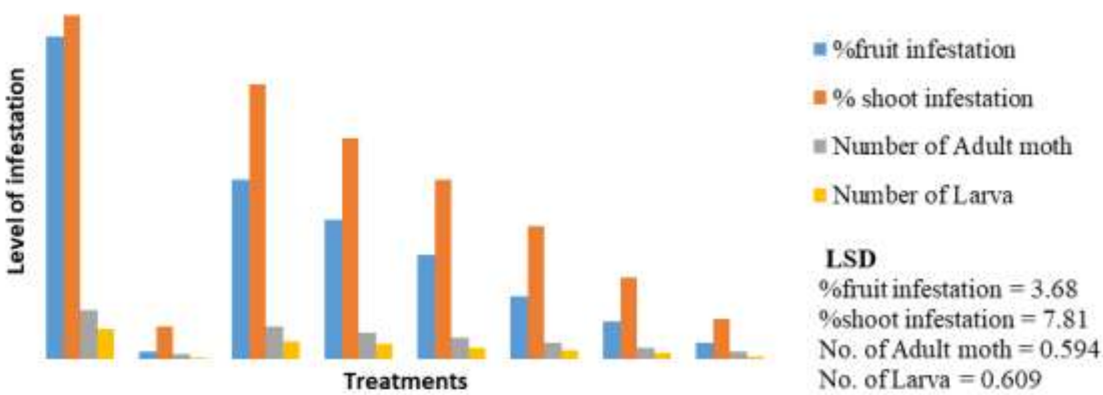

Fig. 1: Effects of treatments on the infestation of EFSB on *S. gilo*

The CYP also had the lowest percent shoot infestation of 7.87%, though it varied significantly from the other treatments but had statistical similarity with T_{27} which recorded percent shoot infestation of 9.74% (Figure 1). The highest percent shoot infestation of 82.14% was recorded at the control plot, and this differed significantly from the other treatments. The highest number of adult moth of *L. orbonalis* (11.761) was observed at the control plot, and this varied significantly from the

ISSN: 2814-0508

other treatments. The lowest number of the adult moth (1.376) was recorded at the CYP which varied significantly from the other treatments except T_{27} (1.852). The number of larva (7.192) was also highest at the control plot which was not statistically similar (P>0.05) with the treatments. The CYP also had a record of the lowest number of larva (0.462) which was statistically similar to the mean value of 0.824 recorded at T_{27}. Uwalaka *et al.* (2018) in their screening of five varieties of eggplant for susceptibility to *L. orbonalis* infestation had reported mean numbers of adult moth and larva of between 0.79-16.15 and 2.06-41.98 respectively, this result confirms that population of *L. orbonalis* thrives on *S. gilo* without control measures.

Table 1 shows the effects of treatments on the level of damage caused by EFSB on *S. gilo*. The treatments were effective in controlling the damage resulting from EFSB infestation. However, there was significant variation (P≤0.05) among the treatments in reducing the damage caused by EFSB. The highest percent reduction in number of holes per fruit, 94.57% was observed at CYP followed by T_{27} (86.34%) while at the control plot, there was 0 % reduction in the number of holes per fruit. However, the CYP differed significantly from the other treatments in reducing the number of holes per fruit. At the second planting season, the highest percent reduction in number of holes per fruit (92.67%) was also observed at the CYP which differed significantly from the other treatments.

Table 1. Effects of treatments on damage caused by EFSB on *S. gilo*

Treatments	Number of holes /fruit /plant	% Reduction in number of holes / fruit	Number of holes / shoot / plant	% Reduction in number of holes / shoot	Number of damaged fruits / plant	% Reduction in fruit damage
C	5.467	0.00	5.560	0.00	76.29	0.00
CYP	0.308	94.57	0.583	87.69	3.87	93.93
T_{10}	2.161	61.85	1.667	57.91	31.04	53.06
T_{15}	2.011	63.90	1.444	65.01	28.98	56.34
T_{20}	1.901	64.98	1.439	65.18	24.64	65.55
T_9	1.684	69.05	1.494	71.15	18.91	73.68
T_{18}	1.386	74.93	0.778	80.13	11.82	83.23
T_{27}	0.798	86.34	0.500	90.47	7.09	88.89
LSD	0.509	3.78	0.422	8.03	6.67	6.93

The percent reduction in the number of holes per shoot was highest, 90.47% at T_{27} which was not significantly different from the CYP (87.69%) but varied significantly from the other treatments (Table 1). The control plot however had a 0% reduction in the number of holes per fruit while among the levels of plant extract, T_{10} had the lowest percent reduction in the number of holes per shoot (57.91%). The highest percent reduction in fruit damage (93.93%) at the first planting season was recorded at CYP which differed significantly from the other treatments except T_{27} (88.89%). The control plot had 0% reduction in fruit damage while among the levels of plant extract, T_{10} had the lowest percent reduction in fruit damage (53.06%), and this varied significantly from the observations made on the other levels of plant extract.

The highest number of holes per fruit per plant (5.467) was obtained at the control plot, and this varied significantly from the treatments. However, the lowest number of holes per fruit per plant (0.308) was observed at CYP but this was statistically similar to T_{27} (0.798). In comparing the various levels of the plant extract, T_{27} was most effective against EFSB in reducing the number of holes per fruit per plant, while the T_{10} which recorded the highest number of holes per fruit per plant (2.161) among the levels of plant extract showed the least effect in controlling EFSB against boring holes in the fruit of eggplant. However, the effect produced by T_{10} in reducing the number of holes per fruit per plant was statistically similar to those of T_{15} (2.011), T20 (1.901) and T_{25} (1.684).

The highest number of damage fruits per plant (76.29) was observed at the control plot while the lowest (3.87) was observed at CYP. The control treatment differed significantly from the other treatments in the number of damaged fruits per plant while CPY also varied significantly from the other treatments except T_{27} (7.09). Among the levels of plant extracts, T_{10} had the highest number of damaged fruits per plant (31.04), and this differed significantly from the other levels while T_{27} had the lowest number of damaged fruits per plant (7.09) which was not statistically different from T_{18} (11.82). The highest number of infested shoot (7.71) was

ISSN: 2814-0508

recorded at the control treatment which varied significantly from the other treatments. The CYP had the lowest number of infested shoots (0.96), and was statistically similar to T_{27} (1.18) but varied significantly from the other treatments. However, among the levels of the plant extracts in the first planting season, T_{10} had the highest record of the number of infested shoots (6.60) which varied significantly from the other levels of plant extracts.

Table 2 shows the effects of application frequency on the level of damage caused by EFSB on *S. gilo*. Results showed that the levels of the application frequency varied significantly ($P \leq 0.05$) in the percent reduction in the number of holes per fruit. The highest percent reduction in the number of holes per fruit of 66.84% was observed at 1 WK which varied significantly from the other levels of application frequency, while the lowest percent reduction in the number of holes per fruit (62.02%) was recorded at 3 WK, and it varied significantly from the other levels of application frequency (Table 2).. There was no significant difference ($P \leq 0.05$) among the levels of the application frequency in the percent reduction in number of holes per shoot. However, the highest percent reduction in the number of holes per shoot (67.41%) was obtained at 2WK application frequency while the lowest (63.81%) was obtained at 3WK. The levels of application frequency were also not significantly different in the percent reduction in fruit damage though the highest (66.03%) and lowest (62.14%) percent reduction in fruit damage were observed at the 1WK and 3WK levels of application frequency, respectively (Table 2). The highest (2.015) and lowest (1.909) number of holes per fruit per plant were obtained at the 2WK and 1WK levels of application frequency, respectively though these were not significantly different from the 3WK application frequency.

Table 2. Effects of application frequency on the level of damages caused by EFSB on gilo in the two planting seasons

	% Reduction in damage due to *L. orbonalis* infestation on *S. gilo*					
Application frequency	%Reduction in no. of holes/fruit	%Reduction in no. of holes/shoot	%Reduction in fruit damage	Number of holes/ fruit/ plant	Number of damaged fruits/plant	Number of holes/ shoot/plant
1WK	66.84	63.8	66.03	1.909	22.18	1.571
2WK	64.51	67.41	64.83	2.015	25.74	1.790
3WK	62.02	63.61	62.14	1.97	28.07	1.729
LSD	2.32	NS	NS	NS	4.08	NS

The highest number of damage fruits per plant (28.07) was recorded at the 3WK application frequency which differed significantly from the 1WK application frequency but was statistically similar to the 2WK application frequency. On the other hand, the lowest number of damaged fruits per plant (22.18) was observed at the 1WK application frequency which was not significantly different from the 2WK application frequency (25.74). There was no significant difference ($P \leq 0.05$) among the levels of application frequency in the number of holes per shoot per plant. However, the lowest (1.571) and highest (1.790) number of holes per shoot per plant were observed at 1WK and 2WK application frequency, respectively.

ABSTRACT

Tomato is one of the important vegetable crops. The problem of seedling establishment is found in tomato due to several soil borne diseases. There are many chemical methods available to control these diseases, but use of chemicals deplete the soil micro-environment and causes soil and water pollution and also do not fit within the framework of 'Organic farming'. Seed priming with certain phytochemicals may be an economic and ecofriendly alternative to such chemicals. A study was conducted in Federal College of Horticulture Dadinkowa, Gombe State to study the effect of tomato seed priming with plant extracts. The experiment was laid in a completely randomized design (CRD) replicated three times. In present study, two sources of tomato seeds were primed with extracts of three different plants (Neem seeds, ginger and Cassia alata leaves) and mancozeb which served as a positive check. Different leaf extracts doses of 40% was taken independently for seed priming in the laboratory and nursery conditions. It was found that priming with neem seeds, ginger and Cassia alata, extract had an improvement in seed germination, survival and seedling growth parameters in both conditions. Priming with mancozeb however was most promising in reducing the effect of pathogens in all the parameters. Seed priming with neem extract exhibited highest germination and survival rate (43.33% and 74.00%) and (48.70% and 46.70%) in farmers seed in laboratory and nursery respectively.

Key words: Plant extracts; seed priming; seedling, tomato, germination, nursery, laboratory

INTRODUCTION

Seed constitute the basic input for crop production in phanerogams so that pathogen free healthy seeds are considered as the vital factor for desired plant population and good economic harvest. Seeds are known to be contaminated with diverse fungal micro-propagules, some of them attack the seeds in the field internally contaminating the seed sheaths, tissues of embryo, endosperm and others under storage as a result of environmental conditions of high relative humidity, suitable temperature and high level of seed moisture content. The seed carrying organism's causes manifold loses to the crop and reduced the agricultural productivity (Bhajbhuje, 2013). Seed-borne diseases are able to spread across international borders very easily and are often difficult to identify as their typical symptoms being rare on seed surfaces as economic impact and importance has increased in recent years with regards to many kinds of crop worldwide (Lew-Smith, 2013). Planting infected seeds result in a widespread distribution of diseases within the crop, and an increased count of initial infection sites from which disease can spread. High rate of seed-to-seedling transmission of seed borne pathogens create alarming situation, even a small percentage of infected seed can result in significant seedling infection in the field (Saskatchewan, 2013). Major genera of plant-pathogenic seed borne fungi infect seedlings, some of them causing severe diseases. They limit the ability of plants to produce healthy fruit bearing shoots, causing damping-off, collar rot, stem canker, leaf blight and fruit rot resulting in premature defoliation, reduction in size and quality of fruits, thereby reducing potential yield to the extent of 20-30% (Lew-Smith, 2013). Seed deterioration is an inexorable, continuous and irreversible process, involves succession of seed borne fungal pathogens under storage resulting in loss of seed nutrients, alteration of physio-chemical properties of seeds, loss in seed weight, seed viability and vigour, medicinal properties, aesthetic changes including discoloration, heating and mustiness, cracking and abnormal odors contributing seed losses to the extent of 24% (Bhajbhuje, 1989). The consequences deterioration leading to series of deteriorative changes include membrane degradation, toxic metabolites accumulation, loss of enzymatic activity, lipid autoxidation, failure of repair mechanisms, genetic degradation, reduced productivity, finally loss of germinability or death of seed (Debnath *et al.*, 2012). Some fungal propagules may bring about certain biochemical changes and toxic metabolites that elicit a toxic response such as carcinogenicity, genotoxicity, terrotogenicity, hepatotoxicity, immunosuppression etc. Secondary fungal metabolites are reported to be toxic to man, animals and pose serious health hazard (Jain, 2008; Brakhage and Schroeckh, 2011; Shephard, 2012).

Tomato (*Solanum lycopersicum* L.) belongs to the family *solanaceae* and it is an annual sub-tropical fruit vegetable crop. The crop originated from South America and was introduced to Europe in the 16th Century and later to East Africa by colonial settlers in early 1900 (Wamache, 2005). In Nigeria, tomato plays a vital role in meeting domestic and nutritional food requirements, generation of income, foreign exchange earnings and creation of employment (Sigei *et al*., 2014). The crop is grown for both fresh domestic and export market but there is increasing demand for processed tomato products (Mungai *et al*., 2000).

Tomato crop does well in warm climate with an altitude range of 0 – 2100 m above sea level. It requires rainfall ranging between 760 mm to 1300 mm and deep fertile loam soil that is well drained, with high content of organic matter and a pH ranging between 5-7 (Rice *et al*., 1994). Fruits are used in salads or cooked as a vegetable, processed into tomato paste, sauce and puree. The nutritional value of tomato makes it a widely accepted vegetable by consumers. Fruits are rich in calcium, phosphorus, magnesium, copper, niacin, iron, folate, Vitamin A, B6, Vitamin E, Vitamin B2, Vitamin C, iron and carbohydrates (Wamache, 2005). Furthermore, the fruit has medicinal value as a gentle stimulant for kidneys, and washing off toxins that contaminate the body systems. It improves the status of dietary anti-oxidants (lycopene, ascorbic acid and phenols) in diet (George *et al*., 2004). Tomato juice is known to be effective for intestinal and liver disorders (Wamache, 2005).

The cultivation of fruit and vegetables in Nigeria is undertaken by small farmers who usually have a small land holding of less than two hectares. As a result, the yield is low and coupled with inadequate postharvest experience, lack of storage facilities and postharvest diseases have made fresh tomato fruit unavailable abundantly all year round in the market in the country. The lack of postharvest management experience, sanitation of the environment of the farm and problem of handling and transportation may lead to pathogen infection which affects the quality of tomatoes. Large quantities of fruits and vegetables are produced and staggering yield figures are quoted as annual production. For example, 6 million tonnes of tomatoes was reported as the annual yield (Idah *et al*., 2007). However, it is the amount of the produce available to the consumer that is more important.

The major constraints to production in Nigeria are; pest and diseases, seed, rainfall, marketing, postharvest losses etc. Amongst the production constraints, pest and diseases are the major ones. The wilt diseases of tomato caused by *Alternaria solani* is one of the devastating diseases of tomato and can reduce yields of the crop significantly and above- all, largely seed transmitted. World-wide, there are numerous reports on seedborne fungi of tomato (Neegaard, 1977; Surayanarayana, 1978). Seedborne fungi are of considerable importance due to their influence on the over-all health, germination and final crop stand in the field. Farmers have to deal with significant losses due to infections by serious seedborne pathogens on their plants, which may start from germinating seed, seedling in the nursery, matured plants in the field and proceed till the products are harvested and fruits and seeds stored. Significant crop losses due to seedborne pathogens have been recorded. Pimentel and Perkins (1980) for example, estimated total world food losses at about 45% due to diseases. The Commonwealth Agricultural Bureaux in their thirty-ninth annual report of 1968 estimated that losses due to diseases alone in the tropics are of the order of 10-13% (CAB, 1968).

Seed treatments for the control of soil-borne seedling diseases have generally met with failure. The only hope of controlling such diseases by seed treatment is that a sufficient quantity of fungicide be carried on the seed into the soil to protect the seedling until it becomes well established. Certain types of seed; such as -the tomato, will ·carry large quantities of material, but, when highly toxic compounds are used, there is almost always considerable damage done to the seed.

The control of seedborne pathogens is the first step in any agricultural crop production and protection programme. Attempts have been made to reduce seedborne infection by chemical treatment of the seeds and some successes have been reported. Messiaen (1992) reported that dressing seeds with non-systemic broad spectrum fungicides such as Thiram, Maneb, Mancozeb, Difolatan, etc at rates of 2-4g a.i/kg of dry dust to very wrinkled hairy seeds of tomato and carrots can kill superficial fungi of spores of *Fusarium* species and *Alternaria* species and can protect seedlings before emergence against *Pythium* species. Though, chemical controls of seedborne pathogens have been very successful, however, chemical pesticides have the additional potential disadvantages of accumulation in the ecosystem and of induction of pesticide resistance in pathogens (Adeniji, 1970, Okigbo and Ikediugwu, 2000; Okigbo, 2004). There is also the problem of lack of expertise in the safe handling of chemical pesticides amongst most of the farmers. It is therefore, necessary to search for seed quality control measures that are cost effective, ecologically sound and environmentally safe to eliminate or reduce incidence of pathogens of economic importance to increase both seed germination and yield of plant crops.

In recent years much attention has been given to non-chemical systems for seed treatment to protect seeds against many plant pathogens (Nwachukwu and Umechuruba, 2001). Anti-fungal activity of different plant extracts has been reported earlier by several investigators against a number of plant pathogens (Hassan *et a*l, 2005; Yang and Clausa, 2007). However, information on management of seedborne fungal pathogens using botanicals on the major vegetable crops is generally lacking. There is therefore the need to investigate into the effect of different botanicals that will reduce or eliminate the incidence of plant pathogens and increase yields of crops. The main objective of the study is to assess the presence and significance of pathogenic fungi on tomato seeds collected from the study area and the possibility of controlling these pathogens using botanicals.

MATERIALS AND METHODS

Experimental Area

The experiments were set out at the Pathology Laboratory and screen house, Federal College of Horticulture Dadinkowa, Gombe State.

Seed Health Testing

Tomato seeds were collected from tomato growers and commercial seed companies. Fifty out of the tomato seed samples collected were plated using the Blotter method at the Crop Protection Laboratory, Modibbo Adama University of Technology Yola, as recommended by Mathur and Kongsdal (2003). The petri-dishes with seeds were arranged in seed trays and incubated for 7 for 12 hours alternating cycles of light (near ultraviolet NUV or florescent daylight) and darkness to enhance sporulation of seedborne fungi. Each seed sample at the end of the incubation was examined thoroughly under stereomicroscope for the growth of fungi. Fungi found associated with seeds were carefully examined and identified based on 'habit characters' (Mathur and Kongsdal, 2003). Slide preparation of fruiting structures, such as conidia borne in conidiosphere, spores held together in spore masses, sporodochia, and acervuli, pycnidiospore in pycnidia, ascospores in perenthecia were examined each using compound microscope to confirm their identity using reference publication (Mathur and Kongsdal, 2003). Records were then taken on incidence and infection percent of the seedborne fungal pathogens identified on seeds.

Preparation of plant extracts

Fresh ring worm plant (*Cassia alata)* leaves and neem (*Azadirachta indica*) seeds were collected within the college environment, while ginger (*Zingiber officinale)* rhizomes and wettable mancozeb powder were purchased in Gombe main market and Agro-chemical stores respectively. Aqueous extracts of each of the plant materials were prepared as recommended by Okigbo and Nmeka (2005).

Neem seed extract

To prepare the solutions, eighty grams of de-pulped dry neem seeds, was weighed using the electronic weighing machine. The seeds were then ground in a blender with 200 ml distilled water. These were vigorously stirred and left to stand for one hour. The solutions were later filtered through layers of muslin cloth. A concentration of 40% of the neem seed extracts was then prepared.

Ginger rhizome

Fresh ginger or *Zingiber officinale* rhizomes were washed and scrapped-off the outer-coverings/skins. Also 80 grams of the scrapped ginger rhizomes was weighed using the laboratory digital weighing machine. This was chopped into pieces and separately ground in a blender with 200 ml of distilled water. It was vigorously stirred and left to stand for one hour. The solutions were filtered through muslin cloth and concentration of 40% of ginger rhizome extracts was prepared.

Cassia alata extracts

Fresh leaves of *Cassia alata* were washed in the laboratory with tap water; 80 g of the washed fresh leaves was weighed using the laboratory weighing machine. The leaves were ground in a blender with 200 ml of distilled water. These were vigorously stirred and left to stand for one hour. The solutions were filtered through muslin cloth. Concentrations of 40% of *Cassia alata* extracts were prepared.

Seed treatment using plant extracts

Samples of the infected tomato seeds were treated with each of the plant extracts by soaking the seeds in each of the concentrations for 12 hours. Treated seeds were dried on clean sheets of paper overnight under room conditions. Seeds were also soaked in 3% concentrated aqueous Mancozeb solutions for 12-hour period and dried under the same conditions similar to the other treatments, while untreated seeds (seeds soaked in distilled water) serving as the control.

Determination of the effects of plant extracts on percent incidence of fungal pathogens and seed germination

Three replicates of 50 seeds per Petri-dish for each of the treated tomato seeds including the controls were plated using the Blotter Method as recommended by Mathur and Kongsdal (2003). They were then observed for 10 days and then examined for seedborne pathogens. Records on incidence of seedborne fungi and germination of treated seeds were taken.

Preparation of plant growing media

Top-soil was steam pasteurized at the Horticulture Department of the Federal College of Horticulture Dadinkowa. Seed sowing pans filled with sowing mix made up with the pasteurized top-soil and fine river sand at the ratio of 2:1 was arranged randomly in the Screen House.

Sowing of the treated tomato seeds

The trial was arranged in a Completely Randomized Design (CRD). For each of the treatments, three replicates of 50 seeds were sown making a total of 250 seeds for each treatment. Sowing was done by the broadcast method and fine sieved pasteurized top-soil was spread evenly on seeds before watering using a watering can and a fine netted screen was used to cover all the bowls containing the treated sown tomato seeds. Watering of germinating seedlings was done every other day with equal amounts of water in the screen house. Records on germination, seedling mortality, and seedling population were taken at 30 days after sowing.

Growing tomato seedling under fine netted screen

Parameters studied

Seed health testing

Data on the incidence and severity of pathogenic fungal infection was collected by examination of incubated seeds under stereomicroscope and compound microscope as recommended by Mathur and Kongsdal (2003).

Determination of effect of plant extracts on incidence of seedborne fungi

The Blotter Method of Mathur and Kongsdal (2003) were used to determine the effect of plant extracts on incidence of important fungal pathogens. This involved plating treated seeds, i.e. 3 replicates of the 5 treatments at the concentration levels of the plant extracts and the recommended Mancozeb (fungicide) and the controls. Observations for the incidence of important fungal pathogens were made under microscope at the end of the incubation period. Records on incidence will be taken using the standard recording sheets.

***Effects of plant extracts on percent seed germination (Laboratory* experiment)**

Records on percent germination were made through counting of normal, abnormal seedlings, freshly un-germinated, hard and dead seeds per treatment in the Laboratory.

Effects of plant extracts on percent seed germination (Screen house experiment)

Standard germination test

Three replications of 50 seeds of each treatment were counted and sown in free drainage plastic bowls of 35cm diameter filled with the sowing-mix' mixed up with the sterilized top-soil and a fine river sand in the ratio of 2:1. Germinated seedlings were counted at 14 days after sowing. Seeds were considered germinated when the radical has emerged from the seed coat with the cotyledons partly or fully exposed.

Effect of plant extracts on seedling mortality and seedling population

The method of Daftari and Verma (2006) was used to determine the effect of plant extracts on seedling mortality and seedling population per treatment. This involved the count of dead and dying seedlings due to infections by seedborne fungi associated with the seed for seedling mortality, while seedling population per treatment were determined by counting the number of surviving healthy seedlings. Records were then taken on seedling mortality and seedling population per treatment at 3 and 4 weeks after sowing respectively.

ISSN: 2814-0508

Statistical analysis of Data

Analysis of variance (ANOVA) was performed on all the data collected in respect of parameters studied on effects of plant extracts and separation of treatment means was done using the LSD at 5% level of significance.

RESULTS AND DISCUSSION

Incidence of fungal species on tomato seeds

Out of the fifty seed samples tested for seedborne fungal pathogens, a total of 4 genera of 6 species of fungi were recorded (Figure 1). The mean percentage incidence and percent severity of seedborne fungi of tomato revealed by the Blotter Method are given. The fungal pathogens recorded were *Aspergillus flavus, Aspergillus niger, Colletotrichum dematium, Penicillium spp, Rhizopus spp* and *Fusarium solani.*

The Blotter Method results revealed that apart from *Aspergillus flavus, A. niger, Penicillium spp and Fusarium solani* all other fungal pathogens were recorded in the farmers with a mean incidence of 2.00 percent. The storage fungus (*Aspergillus flavus*) recorded the highest mean infection percentage of 4 percent, while the lowest mean infection of 0.3 percent was recorded by *Fusarium Fusarium solani.* In the seeds collected from vendors, apart from *Rhizopus spp and Colletotricum dematium* all other fungal pathogens were recorded with a mean incidence of 0.92 percent. *Aspergillus flavus* recorded the highest mean infection of 4 percent, while *Fusarium solani* recorded the lowest mean infection of 0.3 percent.

The highest percentage fungi incidence as well as severity on tomato seeds collected from different farmers may be attributed to inadequate seed drying by most tomato farmers. It may also be attributed to their storage environment (i.e. under high storage humidity and temperatures). In contrast, the lowest incidence of fungal pathogens recorded from vendors' seeds may be attributed to the proper drying of extracted tomato seeds before storage. Of the fungal species identified, *Fusarium spp* and the storage fungi (saprophytes), for example *Aspergillus spp* were found to be predominant. Similar reports have been reported by Orlova *et al*. (1982), Marcinkowska (1982) and Huang and Sun (1986) who found that *Alternaria alternata, Aspergillus flavus, Aspergillus niger* and *Fusarium oxysporum* were predominantly associated with tomato seeds.

Aspergillus, Rhizopus and *Penicillium* sp. are probably not pathogenic pathogens on tomato. They are however, storage fungi (saprophytes). Harman and Pfleger (1974) and Kulik (1973) reported that *Aspergillus* sp. have no effect on germination of tomato seeds. Of the high incidence of storage fungi, these conditions were found to be as a result of their pre-treatment of their seeds and farmers' storage condition of their seeds.

Effect of plant extracts on percentage seed germination of tomato in the screen house

The results of the effects of plant extracts on percentage seed germination of tomato in the laboratory and screen house is presented in Table 1. The result shows highly significant ($P<0.05$) differences among the extracts for seeds collected from farmers. Results of the study for in-vivo tomato seed was almost similar as obtained by the in-vitro seed germination test. Kuhn and Hargreaves (1997) reported that substances found fungicidal in-vitro, in almost all cases kill the fungus in-vivo and could improve upon subsequent seedling growth when used properly in the seed treatment. In the comparison for example, seed treated with mancozeb recorded the highest percentage germination of 77.30 percent just like the in-vitro experiment with the highest percent (83.30%). Reasons for the high percentage germination by mancozeb treatment may be attributed to the suppression of fungi incidence and above – all, offered a better protection of embryos of the treated tomato seed from damage by *Fusarium moniliforme*.

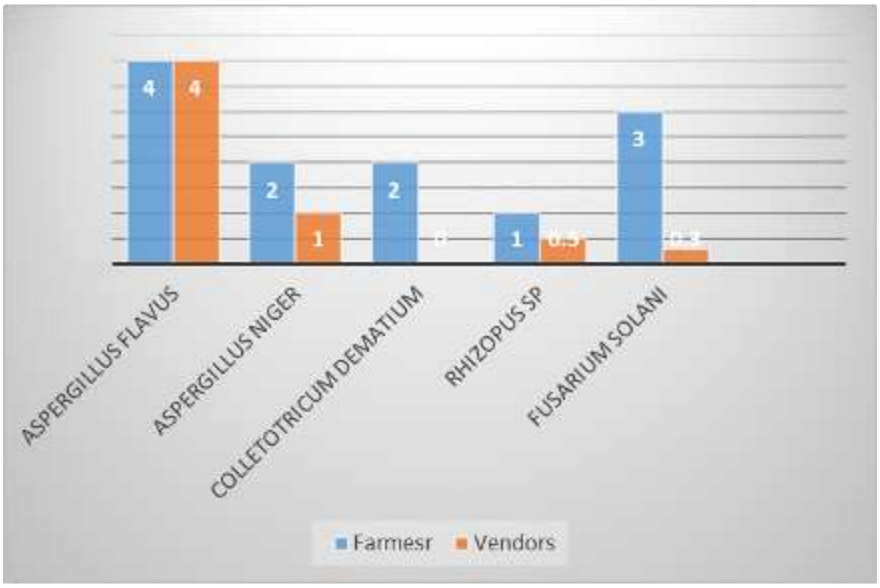

Figure 1. Mean percentage incidence of fungal pathogens on tomato seeds collected from farmers and vendors

Table 1. Effect of plant extracts on percentage seed germination of tomato in the laboratory and nursery

Treatment	Laboratory		Nursery	
	Farmers Seed	Vendors Seed	Farmers Seed	Vendors Seed
Mancozeb	59.33	77.30	77.30	83.30
Neem Seed	43.33	64.00	74.00	54.70
Ginger	40.00	68.70	62.00	64.70
Cassia	36.00	62.00	66.70	80.00
Control	32.67	38.70	38.70	60.30
P<F	<0.001	<0.001	<0.001	0.019
LSD (0.05)	6.904	11.850	12.810	16.700

Effect of plant extracts on percentage seedling mortality of tomato

The result for the effect of plant extracts on percent seed mortality of tomato is presented in Table 2. Results of the study on seedlings mortality indicated significant differences ($P<0.05$) for the effects between plant extracts. Significant reductions of tomato seedlings were therefore observed. Mancozeb achieved the highest of seedling mortalities both in the laboratory and in the screen house. One of the reasons being that, earlier results indicated that mancozeb had some inhibitory effects and that probably could have accounted for the significant reductions. Similarly, results of the study also indicated that extracts of neem seeds compared favourably to mancozeb to achieve control in tomato seed. The reasons may be due to its greater quantities of antifungal activities and that could have contributed in achieving a better control than the other plant extracts. Infected seed is less viable, has low germination, reduced vigour and reduced yield (van Gastel, 1996). Wilting and death of shoot in cucurbits caused by *Fusarium moniliforme* has been reported by Palodhi and Sen (1980).

Table 2. Effect of plant extracts on seedling mortality of tomato in laboratory and nursery conditions

Treatment	Laboratory		Nursery	
	Farmers Seed	Vendors Seed	Farmers Seed	Vendors Seed
Mancozeb	12.70	18.70	24.00	27.37
Neem Seed	14.00	19.30	25.30	33.30
Ginger	16.70	23.30	24.00	30.30
Cassia	13.30	27.30	32.00	33.30
Control	45.30	50.00	44.70	50.70
P<F	0.002	0.007	0.004	0.005
LSD (0.05)	6.50	14.310	10.880	10.630

Effect of plant extracts on seedling population (%) of tomato

Results of the study revealed that there were significant differences (P<0.05) for the effects between plant extracts for both laboratory and screen house experiments. The results of the study showed that mancozeb gave the highest seedling population (39.30% and 58.70%) in the laboratory and (52.70% and 58.70%) in the screen house (Table 3). It is possible that mancozeb might have possessed greater and stronger anti-fungal activities that probably remained with the seedlings throughout the growth period to offer better protection against seedling mortality. Secondly, seeds treated with mancozeb gave the same good percentage germination at the end of the study period. Thirdly, mancozeb did not encounter serious seedling mortality incidence unlike *Cassia alata, Zingiber officinale* and *Azadirachta indica* extracts which recorded significant percentage seedling mortality. This work is in agreement with the findings reported by Sinnadurai, (1992) that optimum plant densities can influence increased yield and one of several means of achieving this is through the use of good quality seed (Asuboah, 2009). Quality seeds can also be obtained through the use of effective seed treatment method (Asuboah, 2009).

Table 3. Effect of plant extracts on seedling population (%) of tomato in the laboratory and nursery conditions

Treatment	Laboratory		Nursery	
	Farmers Seed	Vendors Seed	Farmers Seed	Vendors Seed
Mancozeb	39.30	58.70	52.70	58.70
Neem Seed	29.30	44.70	48.70	46.70
Ginger	22.70	45.30	42.70	37.30
Cassia	22.70	34.70	30.00	34.70
Control	7.30	22.00	20.70	22.00
P<F	0.019	<0.001	0.002	<0.001
LSD (0.05)	9.250	16.650	9.810	14.400

CONCLUSION

It can be concluded from this work that the use of neem seed extract has the potential of controlling the pathogenic fungi of tomato seeds. Generally, the results also indicated that all plant extracts used to treat the seeds did not significantly reduce seed germination and plant mortality of tomato. However, mancozeb was comparably most efficacious in the control of pathogenic fungi. Tomato farmers should therefore use neem seed extract for seed priming.

ABSTRACT
Herbal fungicides are mostly used to control plant disease because of their ecofriendly nature and cost effectiveness. The present investigation focuses on the antifungal activity of some plant extracts viz., Chromolaena odorata L, Tetrapleura tetraptera (Taub) and Vernonia amygdalina (Delile) The ethanolic and aqeuous extracts of C. odorata L, T. tetraptera and V. amygdalina were tested at concentrations of 5%, 10% and 15% (w/v) for their in vitro fungicidal activities against Fusarium oxysporum Schlecht causing wilt disease in Tomato. The experiment was arranged in a Completely Randomized Design (CRD) in three replications. The results showed a promising antifungal activity of both the aqueous and ethanolic extracts of these plants against F. oxysporum. The inhibitory activity ranges from 34.4 – 15.4% in aqueous extracts and 39.8 – 18.4% in ethanol extracts. Ethanolic extract of V. amygdalina gave the highest inhibition of 39.8% at 15%, while aqueous extract of C. odorata gave the highest inhibition of 34.4% at 15% mycelial reduction (P< 0.05) and these can be compared to 47.6% obtained from plates impregnated with synthetic fungicide (Mancozeb) while the untreated plates had 100% mycelial growth. The results of the investigation indicated that plant extracts possess antifungal activity that can be exploited as an ideal treatment for future plant disease management.

Key words: Tomato, Fusarium, inhibition, eco-friendly, antifungal

INTRODUCTION

Tomato (*Lycopersicon esculentum* Mill.) belongs to the family Solanaceae; it is the most important tropical vegetable crop widely used throughout the world (Hadian *et al.,* 2011). Tomato is a high-value horticultural crop for the local market and an important dietary component, contributing to improved nutrition and livelihood for both rural and urban population (Waiganjo *et al*., 2006). It grows well in a wide range of soil types which are high in organic matter, well drained with pH range of 5-7.5, and optimum temperatures of 15°C – 25°C (Bawa, 2016). The demand for tomato in developing countries such as Nigeria has increased significantly in the last decade, due to its ability in the prevention of heart diseases and prostate cancer (Jones, 2008) coupled with the treatment of high blood pressure (Andersson, 2002).

However, many constraints affect productivity and quality of tomato among which diseases play a salient role (Pritesh *et al*., 2011). The common diseases of tomato include; late blight, early blight, anthracnose, wilt and canker (Winand *et al*., 1999). Out of these diseases, the wilt and root rot caused by species of Fusarium remain a challenging task in terms of tomato farm managements throughout the world, especially in the tropical region as it accounts for 90 % economic losses (Sahu, 2013). Fusarium wilt is caused by *Fusarium oxysporum* Schlecht or *Fusarium solani;* it is one of the most prevalent and damaging disease wherever tomatoes are grown intensively because the pathogen can persist indefinitely in infested soils which may damage plants upon penetration of the root or basal stem (Agrios, 1997; Ajilogba and Babalola, 2013). The disease caused by this fungus is characterized by browning colouration of the vascular bundles of the stem, yellowed leaves, wilted plants and reduced or even total loss in crop yield (Burgess *et al*., 2008). Apart from causing diseases, they also colonize outer cells of roots as harmless endophytes after the pathogen has killed the root tissues and others live as saprophytes in soil (Fravel *et al*., 2003).

Synthetic fungicides have been used majorly for the control of Fusarium wilt but have been found to be considered hazardous, as it is not easily biodegraded, and the excessive misuse of a wide range of fungicides has led to soil deterioration and subsequently increases the resistant pathogen populations (Özgönen *et al.,* 2001; Bajwa *et al.,* 2003).

There is, therefore, a need to encourage the use of natural products like botanical amendments or botanical extracts for the management of Fusarium wilt disease in tomato plants; this is considered as a substitute method to synthetic fungicides and these may be used for formulating new, safer and ecofriendly fungicides.

MATERIALS AND METHODS

Isolation and identification of Pathogen

Isolation of *F. oxysporum* was done using the direct plating method. Infected tomato stem was washed thoroughly in sterilized distilled water, cut into small pieces with a sterile scalpel, surface-sterilized in 5% sodium hypochlorite, rinsed in three changes of sterile distilled water, air-dried on sterile filter paper and plated on Petri dishes containing Potato Dextrose Agar (PDA) amended with (60mg/ml) chloramphenicol. The inoculated plates were incubated at 26^{o}C ± 2°C. Identification of *F. oxysporum* was done through morphological and cultural characteristics exhibited by the fungal isolate.

Preparation of plant extracts

Botanicals were prepared using the procedures of Amadioha, (1999). Fresh leaves of *Chromolaena odorata*, L. (Siam weed, Ewe Akintola), *Tetrapleura tetraptera* Taub. Preseke, soup perfume, African comb. Aidan) and *Vernonia amygdalina* Delile. (Bitter leaf, Ewuro) were collected and air dried for 14 days after which they were ground with the aid of a mechanical grinder to powder. The two soft sides of *T. tetraptera* fruits were cut into 5cm segments (pulp) before grinding. Two solvents (water and ethanol) were used in extract preparation at 5%, 10% and 15% concentrations. Aqueous extracts were prepared by adding 5, 10 and 15g of leaf and pulp into a beaker and adding sterile distilled water until the 100 ml mark on the beaker. The contents in the beaker were thoroughly mixed and left to stand for 24 hours. Thereafter it was filtered with a Whatmann No.1 filter paper. Ethanol extracts were also prepared as above. All plates were incubated at 28±2°C for 5 days. Measurement was taken as the mean growth along the two axes on two pre-drawn perpendicular lines on the reverse side of plates. Data were analysed using ANOVA and means were compared using Fisher's Least Significant Difference (Fisher's LSD) at 5% Probability level.

In-vitro evaluation of botanicals for antifungal activity

In-vitro evaluation for antifungal activity was conducted using the agar dilution method described by Okhuoya, (2012). Two perpendicular lines were drawn at the bottom of each Petri-dish (Amadioha and Obi, 1999). One (1) ml of extract was introduced into sterile Petri-dishes; PDA was added to the Petri-dishes containing the extracts and gently swirled to ensure homogeneity of mixture. Five (5) mm agar plug of 7 days old *Fusarium oxysporum* culture was placed at the center of each petri-dish containing chloramphenicol amended PDA (at the intersection of the two perpendicular lines), the experiment was arranged in complete randomized design in three replicates. The radial growth was measured at 24 hours' interval for 96 hours and the percentage inhibition was calculated using the following formula:

%age inhibition =Dc- Dt/DC x 100

Where; Dc = Diameter of colony in control plate

Dt = Diameter of colony in treatment plate.

All the data obtained were subjected to analysis of variance (ANOVA) and means were compared using Fisher's Least Significant difference at 5% level of Probability (P>0.05).

RESULTS AND DISCUSSION

The effects of both the aqueous and ethanol extracts of the three plant materials on mycelial growth inhibition of *F. oxysporum* are presented in tables 1 and 2 (P>0.05). Percentage inhibition of mycelial growth of *F. oxysporum* varied with the type of plant materials, solvent of extraction and extract concentration. It was also observed that reduction in mycelial growth increased with duration of incubation (P>0.05). Among the plant extracts, aqueous extract of *Chromolaena odorata* gave the highest mycelial reduction (34.37%) at 15% concentration. However, there was no significant difference in mycelial reduction between the aqueous extracts of *T. tetraptera* and *V. amygdalina* at the same concentration (15%) and recorded significantly lower mycelial reduction compared with *C. odorata* extracts. Mancozeb a synthetic fungicide inhibited mycelial growth (45.76%). At 15% ethanolic extract concentration, *V. amygdalina* gave the highest mygelial reduction (39.80%), while at 10% concentration ethanolic extracts of *C. odorata* and *V. amygdalina* gave similar comparable (35.62% and 34.64% respectively) effect on mycelial reduction while the ethanolic extract of *T. tetraptera* gave the least activity (18.43%) in reducing mycelial growth of *F. oxysporum.*

The presence of antifungal active ingredients in the leaves of selected botanicals was demonstrated in this study as it was indicated in their ability to inhibit the growth of *F. oxysporum* in culture. The antifungal activities of different plant species and their importance as possible sources of natural fungicides has been reported, the results obtained in this study confirmed the previous studies showing the antifungal activities of leaf extracts *C. odorata* on *L. theobromae* (Adejumo, 2000; Adeniyi and Joseph, 2015). The aqueous extract of *V. amygdalina* leaves can inhibit the growth of *Fusarium moniliforme* on seeds of maize (*Zea mays*) as well as mycelial and conidial growths of *Colletotrichum gloeosporioides* in rubber tree (Ogbebor *et al*., 2007; Owolade *et al*., 2000; Suleiman *et al*., 2008).

The effectiveness of the extracts increased with increase in concentration and maximum inhibition was recorded at 15%. The mycelial reduction activities of the extracts were solvent and concentration dependent. This is in agreement with the report of Ilondu (2012) and Chiejina and Ukeh (2013) who indicated that increase in the antifungal activities had corresponding increase in concentration of plant extracts. Edward, 2015 had reported the effectiveness of *C. odorata* on Cassava rot disease. Umana et al., 2016 had also reported complete inhibitory activities of *T. tetraptera* on *Penicillium* species in *Arachis hypogaea*. The differences in the effectiveness of the extracts could be attributed to the differences in their active ingredients and ability of the extraction solvent to release the active components in the plants (Onifade, 2002; Okigbo et al. 2009). The fungitoxic effects of these plant extracts indicate their potentials and this could be explored as part of sustainable Integrated Pest Management (IPM) strategy to manage Southern blight on tomato.

ABSTRACT

The most common challenge in carrying out studies on plant extract is the contamination due to bacteria, fungi, and mould, which may occur during various stages of extraction and following experimental procedures. Hence, this study investigated the effects of two sterilization methods on three sawdust (Cola nitida, Anogeissus leiocarpus and Gmelina arborea) extracts on antifungal activity against Southern blight pathogen (Sclerotium rolfsii). The experiment was conducted in the Pathology laboratory of National Horticultural Research Institute (NIHORT) Ibadan, Nigeria, and laid out in a Completely Randomized Design (CRD) with 3 replicates. Three concentrations (5, 7.5, and 10 %) and two methods of sterilization (autoclave and Ultraviolet light) were employed to sterilized the extracts and fungitoxicity determined. The in vitro results showed that highest mycelial growth inhibition was recorded at 10 % on all the extracts, however, UV sterilized extract gave higher mycelial inhibition throughout the period of observation and values obtained were significantly comparable with values observed on commercial fungicide (mancozeb at 2.5 g/l) treated plates. It was concluded that the sawdust extracts used at highest concentration gave promising prospects for the management of Southern blight. However, there is a need to further evaluate the antifungal potential of these sawdust on the field to establish their antifungal effectiveness on Southern blight of tomato.

Keyword: Fungitoxicity, autoclave, ultraviolet, sawdust, blight

INTRODUCTION

Sclerotium rolfsii Sacc. is one of the most destructive soil inhabiting pathogens and causes heavy loss to over 500 host plants belonging to 100 different families (Liamngee, 2015). In severely infected field, loss ranges from 10 to 25 per cent and sometimes reaches up to 80 per cent. (Aycock, 1966; Punja, 1988) The hazards involved in using chemical fungicides and the development of resistance to synthetic fungicides by plant pathogenic organisms, make alternative control desirable. This experiment seeks to evaluate the effect of sterilization methods on antifungal activity of sawdust extract in the management of *S. rolfsii*.

MATERIALS AND METHODS

Sawdust was collected from Sango sawmill in Ibadan metropolis, Oyo state, Nigeria. Fifty, 75 and 100 g of each sawdust type was soaked in 1 L sterilized distilled water for 24 h and sieved through four layer sterilize cheese cloth to obtain 5, 7.5 and 10 % w/v) concentrations respectively. The prepared extract was sterilized either in autoclaved at 1.1 kg/cm^2 pressure at 121˚C for 15 minutes or ultraviolet light (254 nm) for 30 minutes.

Sterilization of materials

The inoculating needle and the cork borer were sterilized by flaming using a spirit lamp. The glass wares such as the petri dishes, the conical flasks and test-tubes were sterilized in a hot air oven at 160^o C for 2 hours. The table was sterilized using 70 % alcohol for 30 minutes.

Isolation of pathogen

Sclerotium rolfsii was isolated from infected tomato stem collected from NIHORT vegetable experimental field, washed with clean water and was cut into about 5cm segments. One percent sodium hypochlorite (1% NaOCl) was added for 1 minute and rinsed in four changes of sterilized distilled water and was left to dry for 30 minutes at 28 + 2°C. The segments were then plated on sterilized Potato Dextrose Agar (PDA) in petri dishes. Inoculated petri dishes were incubated at 28 + 2°C for 4 days and observed daily for fungal growth. Subcultures were made by transferring hyphal tips from the colony edge of the mixed cultures to fresh plates of PDA using flame sterilized inoculating needle and incubating at 28 + 2°C to obtain pure culture of *S. rolfsii*. Colony characteristics were examined with the aid of a microscope. Cultural and morphological

ISSN: 2814-0508

characteristics observed were recorded and compared with typical conidial structures using identification keys described by Barnett and Hunter (1999) and Watanabe (2002).

Three ultraviolet light and autoclave sterilized sawdust extract were screened against *S. rolfsii in vitro* to examine the inhibitory effect on mycelial growth and sclerotial production evaluation of antifungal activities of the extracts, Autoclaved sawdust extract was obtained by autoclaving at 121°C for 15 minutes while the UV sterilized extract was obtained by exposure of the extract to 280 nm wavelength for 45 minutes. The prepared sterilized extracts were used at desired concentrations of 5, 7.5 and 10 % and introduced using standard procedure replicated for each treatment. PDA without plant extract and with commercial fungicide (Mancozeb 80 wettable powder) served as control. Each plate was inoculated with a 5 mm diameter mycelial disc taken from 5-days-old culture of *S. rolfsii* grown on PDA. The inoculated plates were incubated at 25 +2^{o}C and radial mycelial growth was recorded at 24 hours' interval for 4 days. The experiment was arranged in completely Randomized Design (CRD).

The fungitoxicity in terms of percentage inhibition of mycelial growth was calculated using the formula adopted by Shikha *et al*., (2013), that is;

Where; dc = Average increase in mycelial growth in control; dt = Average increase in mycelial growth in treatment.

Data obtained were analysed using Analysis of variance (ANOVA) and the means were separated using Least Significant Difference (LSD) at p = 0.05.

RESULTS AND DISCUSSION

Mycelial growth inhibition was significantly different (P ≤ 0.05) in autoclave and UV sterilized extract (Figure 1- 3). Generally, mycelial growth inhibition was low at reduced concentration (5 %) whereas, it was significantly higher at 7.5 and 10 % extract concentration. At 24 and 72 h, mycelial inhibition was found to be 62.7 and 45.82 % and this was significantly (P ≤ 0.05) comparable to what was observed on plates treated with mancozeb which recorded 87.46 and 60.78 % respectively in UV sterilized *C. nitida* extract while autoclave sterilized extract gave mycelial growth inhibition of 57.4 and 38.00 % at 48 and 72 hours and this was found to be significantly (P ≤ 0.05) similar to 48.04 and 38.33 % recorded on mancozeb treated plate at 2.5 g/l, the sane trend was observed at 96 h (Figure 1). *Anogeissus leiocarpus* autoclaved and UV sterilized aqueous extract exhibit significantly different effect on mycelial growth of *S. rolfsii* (Figure 2). In UV sterilized extract at 24 h and 48 h mycelial growth inhibition at 5 and 7.5% concentrations were not significantly different (P ≤ 0.05), likewise between 7.5 and 10 %.

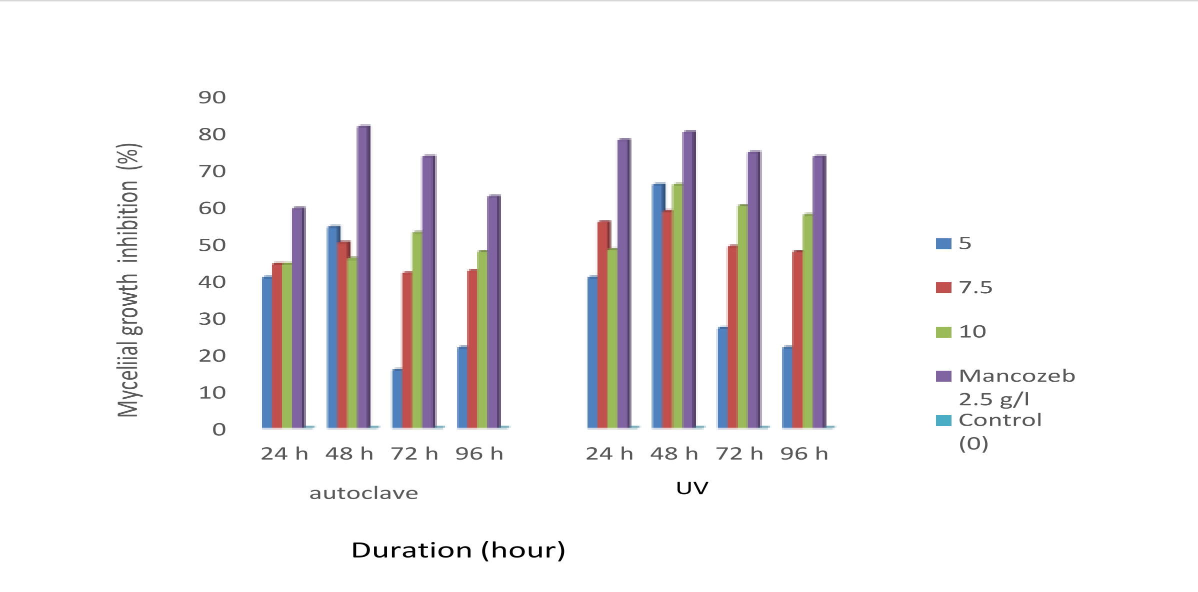

Figure 1. Effect of *C. nitida* extract on mycelial growth of *S. rolfsii* Sacc

However, highest mycelial growth inhibition was recorded at 10 % concentration throughout the period of observation and values obtained were significantly comparable with values observed on mancozeb treated plate (Fig 2). The effect of aqueous *Gmelina arborea* sawdust extract on *S. rolfsii* mycelial growth inhibition is presented in plate 3. In autoclave sterilized extract, highest mycelial inhibition 73.08 % on plate impregnated with 10 % concentration and this was comparable to 67.23 and 65.03 % taken on plates with 7.5 concentration at 24 h. It was observed that at 96 h mycelial growth inhibition (52.07 %) obtained on plate treated with 10 % extract was significantly higher than other concentrations but comparable to 57.115 % recorded on mancozeb impregnated plate. However, in UV sterilized extract highest mycelial inhibition (49.61 %) was recorded in plate with 10 % extract when compared with other extract at 96 h (Fig. 3).

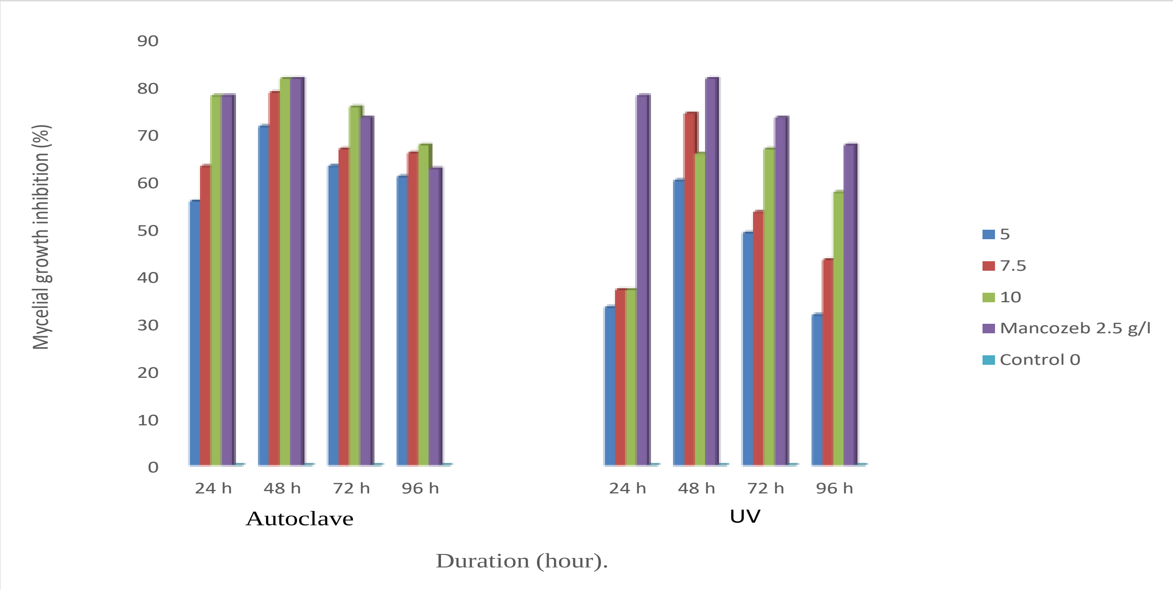

Figure 2. Effect of *A. leiocarpus* extract on mycelial growth of *S. rolfsii* Sacc

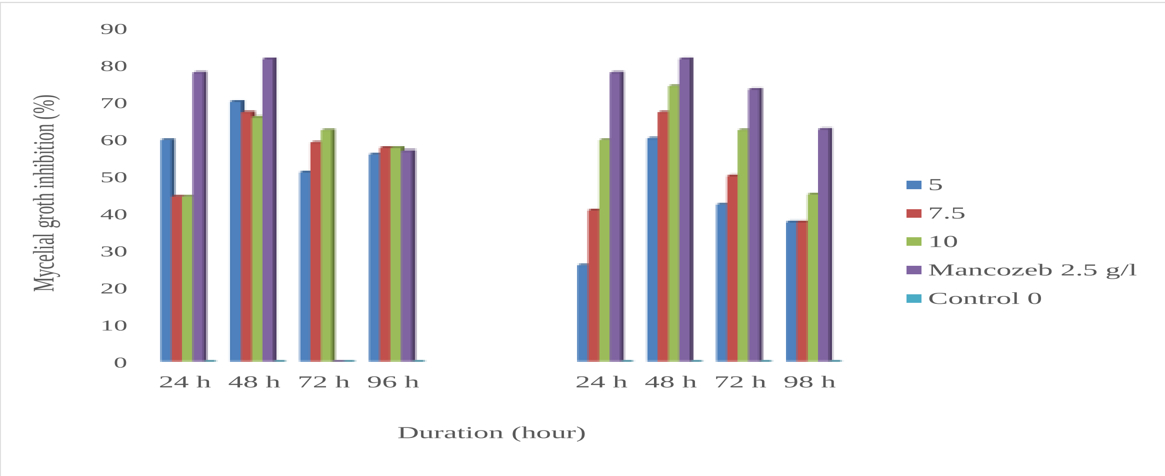

Figure 3. The effect of aqueous *Gmelina arborea* sawdust extract on *S. rolfsii*

Studies have shown that UV at 254 nm is effective against all pathogens, natural microbiota, moulds, and yeasts. Ultraviolet sterilized extracts from *Datura metel* L. at wavelength of 250-280 nm has been reported to enhance the potency and antimicrobial effect when the extracts were evaluated against 3 strains of pathogenic organisms (Abd-Allah *et al*., 2018). Ultraviolet radiation at 280nm for 45 minutes have also been reported to preserve the chemical and molecular components in Spathiphyllum plant (Metwally *et al*., 2019). Also, extracts of *C. nitida* has been reported to contains reasonable amounts of phenolic compounds including bioflavonoids, xanthones and benzophenones which reduced the mycelial growth of *Aspergillus niger*, *Aspergillus fumigatus* and *Mucor racemosus*. The effectiveness of *A. leiocarpus* sawdust extract in this study is corroborated by the findings of Mann *et al*. 2008, who reported that the root extract of *A. leiocarpus* was effective in inhibiting the growth of *Aspergillus* and *Penicillium* species. The root extract of *Gmelina arborea* have been reported to inhibit the growth of *Aspergillus niger*, *Penicillium notatum* and *Candida albicans* (Charu and Vinita, 2017) and also served as botanical fungicide (Okunji *et al*., 2007, Okoko, 2009). The results obtained from this study on the antifungal potential of the sawdust extract of *Cola nitida, A. leiocarpus* and *G. arborea* is corrobated by the report of Beckley and Awoyemi, (2021). The antifungal activity of constituents from the heartwood of *G. arborea* against *Trametes versicolor* and *Fomitopsis palustris* was also reported by Kawamura *et al* (2005).

CONCLUSION

This study revealed that sterilization method with high temperature such as in the autoclave could seriously damage the structure of bioactive compounds in extracts, which, in turn, decrease the activity (Watanabe 2002), and that higher concentrations (> 5%) of the plant extract should be considered for use if antifungal potential is expected (Adesegun *et al* 2014). Ultraviolet light sterilization is a better alternative for plant extract to avoid contamination and maintain the antifungal potential.

ABSTRACT
The nematicidal effect of aqueous Azadiractha indica leaf extract and a standard synthetic nematicide, carbofuran were evaluated for their effect on pathogenicity of Meloidogyne spp on growth and yield of okra. The experiment was carried out during the 2019/2020 cropping season. There were seven treatments and control replicated three times in a Randomized Complete Block Design to give a total of twenty-four plots. Data collected on growth and yield parameter were subjected to analysis of variance (ANOVA) and means were separated using Duncan Multiple Range Test (DMRT) test at 5% level of probability. The results obtained indicated that effect of T7 (carbofuran) on okra was significantly better than all other treatments tested in both growth and yield characters. Also at harvest, galling was significantly lower in carbofuran treated plants compared to the neem treated plants. The control plants were most galled with poor yield and had stunted growth. The moderate concentrations of both neem (100ml aqueous, 200ml aqueous, 100ml ethanol, 200ml ethanol, 25g neem powder, 50g neem powder and 0.26g of carbofuran performed significantly (p<0.05) better than control plants in suppressing the effects of root-knot nematode on yield and growth of okra. These suggest that the neem extract have nematicidal property and would be effective in management of root-knot nematodes. Treatment T5 (Powder of neem 25g) had significantly better plant height and was therefore recommended to farmers in the study area, pending further studies.

Key words: Okra, Neem, Carbofuran, Aqueous, Azadirachta

INTRODUCTION
Okra (*Abelmoscus esculentus* (L) moench) belongs to the family Malvaceae. Okra is usually grown in Nigeria for its mucilaginous content. The importance of Okra as a vegetable crop lies in a drawing quality that aids easy consumption of bulky staple food like Gari, Fufu, and pounded yam (Agbogidi and Nweke, 2005). The mucilaginous extract from okra is reportedly useful in curing ulcer as well as the relief of humor hoods and also a dealing agent in sugar processing. (Schippers, 2000) noted that the tender pod contain vitamin A and C traces of B vitamin, Okra provide good source of calcium and other body building minerals that contribute to healthy living and is native of tropical parts of Africa but it is now widely grown in the tropics. The fruit is a long pod, usually ribbed, spineless in cultivated kinds and harvested when three-four inches long. Pods are harvested while still tender and immature. It is a tropical plant, which grows best in warm climate. It is available all year round, with a peak during summer months (Adekunle and Fawole, 2003). The pods grow rapidly being ready for harvest in about 30-40 days (depending on the variety) when grown from seed. But the plants will continue to bloom and produce pods if they are harvested continuously before they get too large. Root-knot nematodes (*Meloidogyne spp*) infect almost all types of pants and may cause considerable damage. During surveys, most vegetable crops including okra were found to be affected with *M. incognita*. Root-knot nematodes (*Meloidogyne spp*) are minute, worm-like animals which are very common in virtually in every environment. They are major pathogens of vegetables in the world, affecting both quantity and quality of marketable yields. With severe infestations of nematode, yields loss ranges between 10-50%, and the use of chemical (synthetic) nematicides have been discourages because of its residual effects and high toxicity to the soil. Nematode management is complicated and difficult and at present, chemical control is employed in many crops to maintain their populations below economic threshold levels (Abad *et al*., 2003, Eapen *et al*., 2005). Therefore, the researcher sorts to compare the effect of neem extract which is a natural nematicide, environmental friendly with synthetic nematicides on the growth and yield of okra infected with root knot nematode.

MATERIALS AND METHODS

Description of Study Location

The experiment was carried out in a section of the Teaching and Research Farm of Kabba College of Agriculture, Ahmadu Bello University, Nigeria during the cropping seasons of 2019/2020. The site is located on the latitude of 07^0 35'N and longitude 06^0 08E and is 435m above sea level, in Southern Guinea Savanna Agro-Ecological Zone of Nigeria. Rainfall spans between April to November with the peak in June. The dry season extends from December to March. The mean annual rainfall is 1340mm per annum with an annual temperature range of 18-32˚C. The mean relative humidity (RH) is 60% (College of Agriculture Meteorological data, 2019). The major soilsin the experimental site are Alfisols and Ultisoils (Babalola, 2010).

The main vegetation of the area is; tall grasses, shrub, some trees, plantains, oil palm, etc. Some parts of the site are used such as cowpea, cassava, maize and tomato being planted.

Field Work

Okra seeds were source from Horticultural section of Kabba College of Agriculture, Ahmadu Bello University. The experiment was conducted using single field of dimension 12m x $8m^2$ which consisted of eight treatments and were replicated three times. The experiment was laid out in a Randomized Complete Block Design (RCBD). The treatments consisted of the followings: T1= Aqueous extract of neem at 100ml, T2=Aqueous extract of neem at 200ml, T3=Ethanol extract of neem at 100ml, T4=Ethanol extract of neem at 200ml, T5=Powder of neem at 50g, T6=Powder of neem at 25g, T7=Carbofuran 1.5kg ai/ha (0.26/stand) and T8=control.

Experimental Procedure

Seeds of Okra were sown on a flatbed; three seeds were planted at a spacing of 60cm x 30cm. The fully emerged plant was thinned down into two healthy plants per stand.

Source of Test Plant and Carbofuran

The text plant, *Azadirachta indica* (neem) was sourced for around Kabba College of Agriculture and synthetic nematicide; (carbofuran) was purchased from KI Bello Agro-Allied Nigeria Limited Muritala way Ilorin Kwara State, Nigeria.

Preparation of Test Plant

Fresh leaves of *Aradirachta indica* were harvested and chopped into pieces using blender. 1 kilogram (1kg) of tested leaves were taken and mixed with 1ltr of water and allowed to soak overnight, which was later sieved to obtain 100% test plant extract. From this 100% test plant extract the different levels of the plant extract were obtained as a treatment for application.

Extraction of Nematode Eggs

Galled root was collected from *celosia argentea* on which a pure culture of *Meloidogyne incognita* was raised. The galled root was washed properly under the running tap in order to get rid of the attached soil. The root was cut into small pieces and shaken with 5% of Sodium hypochlorite solution (NaOCl) (5ml parazone + a 5ml distill water for about 5minutes in a Kilner's jar (Hussey and Barker, 1973) in other to digest the gelatinous matrix encasing eggs. This was carried out at Land Mark University Science Laboratory in Omu- Aran Kwara State.

Inoculation

After fourteen days of planting the experimental plot was inoculated with juveniles of *Meloidogyne*. The size of each plot is 10 by 4 m; the experimental plots were inoculated with 50g of infected root of *celosia angentea* containing 1000 of *Meloidogyne incognita* at juvenile stage which was carried out in the field.

Data Collection

Data were collected from the experimental plots in the field one month after planting. Subsequently, data were collected at weekly interval based on the following parameters: Plant height (cm), was talking with the use of measuring tape, number of leaves was obtained by counting numerically, leaf area (m^2) was taking with the use of measuring tape, stem girth at 30 cm from the base of the plant (cm) was taken with the use of Vernier caliper, average pod weight (kg) this was obtained with the use of weighting scale, pod length (cm) was talking with the use of measuring tape, number of fruit per plant was obtained by counting numerically, Pod diameter (cm) was taken with the use of measuring tape and nematode population was taken at initial stage and final stage.

Data Analysis

Data collected from field experiments were subjected to the analysis of variance (ANOVA) using the SPSS version 21 and where there was a significant difference in their means. The New Duncan's Multiple Range Test (NDMRT) was used to separate them at a 5% level of significance.

ISSN: 2814-0508

RESULTS

In the preliminary phytochemical investigations, it was observed that alkaloids tannins, phenols, flavonoids, terpenoids, sterols, saponins, glycosides and reducing sugar were present in the neem extract (Table 1). These compounds also serve to protect the plant against infections by parasitic nematodes, microorganisms, predations by insects and herbivores, while their odor and flavor are responsible for their pigments (El-Mahmood *et al*., 2008).

Table 1. Phytochemical Screening of Leaf Extracts *A. Indica* in Different Solvent.

Tests	Plant Extracts	
	Aqueous	Ethanol

Phytosterols	+	+
Phenols	+	+

There was significant difference between the treatments for plant height (cm), number of leaves, stem girth (cm), leaf area (m^2). The highest plant height was observed in treatment T5 (36.8cm), powder of neem at 25g, followed by T7 (36.4cm) carbofuran at 0.26g/stand (Table 2). The highest number of leaves, stem girth and leaf area was T7 (carbofuran), followed by T5 (powder of neem 25g). The lowest produced was observed in T8 (control).

Table 2. Effect of Treatments on Growth Parameter

Treatment	Plant height (cm)	Number of leaves	Stem girth (cm)	Leaf area (m^2)
T1- Aqueous of neem 100ml	29.4^b	20.4^a	1.66^a	1.14^c
T2- Aqueous of neem 200ml	26.8^b	19.5^a	1.84^a	1.08^c
T3- Ethanol of neem 100ml	32.1^{ab}	21.6^a	1.96^a	1.11^c
T4- Ethanol of neem 200ml	31.4^{a}b	18.7^a	1.81^a	1.23^{bc}

T8- Control	18.31^c	13.0^b	0.98^b	0.71
LSD	6.31	4.63	0.38	0.26

Average weight of pod (kg), pod length (cm), pod diameter (cm), and number of fruit per plant, were highly significantly better in T7 (Carbofuran 0.26g) compared to all others treatments. T5 have the same pod length (cm) with T7 (6.1). T8 had the lowest average pod weight (kg), pod length (cm), pod diameter (cm), and number of fruit per plant (Table 3).

ISSN: 2814-0508

Table 3. Effect of Treatments on Yield Parameters

Treatment	Average pod weight(kg)	Pod length(cm)	Pod diameter(cm)	No of fruit per plant
T1-Aqueous 100ml	0.71^{b}	4.6^{b}	3.1^{a}	6.2^{c}

T8-Control	0.34^{c}	2.8^{c}	1.9^{b}	3.1^{d}
LSD	0.21	0.73	1.21	2.41

The initial nematode population was collected and the final nematode population was also collected (Table 4). The effect of the treatment uses to control the nematode population was express mathematically as: Efficiency of material use =value of treatment/value of control ×100.The result show that T7 (carbofuran at 0.26g) was 0.71 time better than the control, T3 was 2 times better than control, T1 was 9 times better than control.

Table 4. Effect of Treatment on Nematode Population

Treatment	Initial nematode population	Final nematode population	Efficiency of material used
T1-Aqueous of neem 100ml	1000	126	9.96
T2-Aqueous of neem 200ml	1000	84	6.64

T7-Carbonfuran	1000	09	0.71
T8-Control	1000	1264	

DISCUSSION

The findings of this study showed that both growth and yield parameters were significantly increased in treatments with plant materials and synthetic nematicide (carbofuran) whether infected or not with *Meloidogyne spp* compared to the plant that were untreated with botanicals and carbofuran. This could be as a result of the presence of some active ingredient present in carbofuran and test plant (neem extract). The results also revealed that the chemical components (alkaloids, tannins, phenols, flavonoids, terpenoids, sterols, saponins, glycosides, terpenoids, phenols and reducing sugar) present in *Azadiractha indica* leaf extract are responsible for the nematicidal effect on the root knot-knot nematodes (Saravanapriya and Sivakumar, 2005, Hayat *et al*., 2012, Onyeke and Akueshi, 2012).

These compounds also serve to protect the plant against infectious microorganisms, predations by insects and herbivores, while their odor and flavor are responsible for their pigments (El- Mahmood et *al*., 2008). The results revealed that significant increase in plant growth and yield parameters was observed when neem leaves extract were applied at 25g of powder of neem, 100ml of aqueous of neem and 100ml of ethanol of neem and carbofuran at 0.26gcompared to other doses. The aqueous neem extract and powder of neem improved plant growth parameters of okra over control. Plant growth and yield parameters of okra were improved significantly by all the different doses. These results are in agreement with Ramkrishnan *et al*. (1997) who reported increase in plant growth characters through botanicals as soil amendments. The study supports the findings of other researchers who reported the importance of various soil amendments in reducing plant-parasitic nematodes population to build up resulting in an increase in plant yield (Abolusoro and

Oyedunmade, 2008; Izuogu *et al*., 2015, 2016). The study revealed that the neem leaf extract used had significant nematicidal effects on *Meloidogyne incognita* as it caused a reduction in nematode population in okra compared to control. This is in line with the reports of some earlier researchers who reported that the effect of the different levels of extract on juvenile mortality could be due to the presence of tannins, alkaloids and flavonoids which have been reported to killed nematodes leading to effective reduction in nematode population by botanicals (Adegbite and Adesiyan, 2005), Umar, 2012).

CONCLUSIONS

These findings provided valuable data and information on the need to provide a wide support for nematicidal activity and suggest that the addition of botanicals to soil has potential for development as novel nematicides for the control of the root-knot nematodes. Neem extract incorporated to soil can be recommended as an alternative to nematicides. This knowledge will help in better developing the use of organic materials in the control of plant parasitic nematodes. However, more field trials need to be carried out on this material to test the efficacy under natural conditions.

ABSTRACT

The main delimiting factor in the wide acceptance of Neem (Azadiracta indica A. Juss) oil as a storage biopesticide is its foul sulfurous odour and bitter taste which impinges on the acceptability and marketability of treated produce. To reduce this shortfall, proportional mixtures of neem and palm kernel oils (PKO) were evaluated to test their effectiveness in the control of cowpea weevil (Callosobruchus maculates L.) with the aim of reducing some of the side effects of neem on treated produce. The treatment comprised common bean grains (Phaseolus vulgaris L.) and proportional admixtures of neem oil and palm kernel oil at the following mixtures per 50 g cowpea grains various concentrations: N_0P_0 = No neem, No PKO; N_1 = Neem at 1.0 ml; N_2 = Neem at 2.0 ml; 1N:1P_1 = 10 ml Neem + 10 ml PKO at 1.0 ml; 1N:1P_2 = 10 ml Neem + 10 ml PKO at 2.0 ml; 1N: 2P_1 = 10 ml Neem + 20 ml PKO at 1.0 ml; 1N:2P_2 = 10 ml Neem + 20 ml PKO at 2.0 ml; 1N: 3P_1 = 10 ml Neem+30 ml PKO at 1.0 ml; 1N:3P_2 = 10 ml Neem + 30 ml PKO at 2.0 ml; P_1 = PKO at 1.0 ml; P_2 = PKO at 2.0 ml. A synthetic pesticide (Phostoxin, P_t) at 0.2 g/kg cowpea grain served as the positive control. The treatments were laid out in a completely randomized design (CRD) on a laboratory bench and replicated three times. Data collected on adult bruchid mortality at 24 hours, 48 hrs, and 7 days after infestation (DAI), oviposition counts and percentage damaged grains were compared with the untreated samples. Results showed that grains that received 1N:1P_1, and 1N:1P_2 had significantly higher ($p < 0.05$) adult bruchid mortality, oviposition reduction and significantly lower ($p < 0.05$) grain damage compared to other treated and untreated grains. Their performance was closely comparable to Synthetic pesticide (P_t) as they showed high prospects with the standard positive control (Phostoxin, P_t) treated grains. They could therefore be evaluated further for use as effective bruchid control alternatives in place of the conventional insecticides or sole neem oil treatment.

Key words: Toxicity, Neem oil, Palm kernel oil, Cowpea bruchid, *Phaseolus vulgaris*

INTRODUCTION

Common beans (*Phaseolus vulgaris* L.) is an indigenous African legume crop belonging to the Fabacceae/Leguminosae family. It is an important edible legume crop in many parts of the world especially in tropical and subtropical regions. It has been reported to be of great economic importance in human and animal nutrition. Common beans is used as human food due to its high nutritional content especially protein content (Diouf, 2011). The genus *Vigna* contains about 170 plant species with the largest number occurring in Africa, but some are found in India, Australia and the New world. However, only three species of *Vigna* are important as legumes. Common beans (*Phaseolus vulgaris L.*) is the most important protein-source grain legume for direct consumption in the world (Broughton, 2003). Cowpea originated in the southern and east African region (Adesoya and Ojobo, 2015) but has spread and is now cultivated in more than 100 countries between 40° N and 30° S latitude. Nigeria is the second highest consumer of cowpea in the whole world (Egho, 2009). World production of cowpea was estimated to be 2.27 million tonnes of which Nigeria produces about 850,000 tonnes (about 37%) (FAO, 2002; Adaji *et al*., 2007). Cowpea is of major importance to the livelihoods of millions of relatively poor people in less developed countries of the tropics. FAO, (2001) and Islam *et al*. (2006) emphasized that all parts of the plant used as food are nutritious providing protein and vitamins.

It is widely recognized that one of the major constraints of cowpea production in African is the high incidence of insect pest and disease attacks which cause heavy losses. Zahra *et al*. (2006) reported that all stages of cowpea production were subject to damage and losses due to insect pests leading not only to substantial reduction in yield but reduced quality. What is eventually obtained by the farmer is far below the potential of the crop. According to them high yields of cowpea were largely hindered by insect pest damage and suggested that applying control methods could lead to yield increases. Cowpea suffers heavily from insects, both in the field and in the store. Yield reductions caused by insects can reach as high as 95%, depending on location, year, and cultivar (Carlos, 2000). Infestation begins in the field at low levels. After the crop is placed in storage, the insect population continues to grow until the cowpea is completely damaged. Among the insects which causes serious loss of cowpea seeds during storage is *Callosobruchus maculatus* (bean weevil) and *Bruchidius atrolineatus.* The importance of cowpeas to West African farmers and the destructiveness of the cowpea weevil to stored cowpeas have spurred many researchers and farmers in West Africa to assay a variety of potential protective measures. These include the use of oil, liquid and powdered extracts of pepper seeds, *Piper guineense,* ginger and cashew, sand, ash, plant materials, paprika and various neem products. For thousands of years, experimental knowledge of the use of botanical pesticides for pest control provided means for crop protection in different parts of the world even before the development of synthetic insecticides. Malik and Naqvi (1984); Su (1990); Dunkel and Sears (1998); Wongo (1998); El-Lakwah *et al*. (2002); Jbilou *et al.* (2006); Mamun *et al.* (2009); Hatil (2009) et c. at their various times and locations had worked with different parts of plant and extracts on stored product pests with encouraging results. Their various reports showed that these plant parts exerted their effects in various ways on the target pests including, insecticidal, repellent, development inhibition and ovicidal. Plant materials used in the control of this important pest of cowpea are cheap and sourced readily unlike the insecticides which come with so many attendant associated problems and health concerns. Moreover, peasant farmers and grain merchants can easily handle plant materials than the insecticides. These are why conventional insecticides are not the answer to the insect problems (Carlos, 2000).

The compounds in neem have demonstrated powerful effects against a very broad spectrum of phytophagous insects that compete with us for food and fibre (Grish, 2008). Neem has shown a variety of toxic manifestations, namely: inhibition of insect growth, deformations, inhibition of ecdysis, outright mortality, inhibition of protein synthesis and inhibition of protein transfer. The wide spectrum of toxic modes of action enhances neem's ability to slow down resistance development in phytophagous insects. Lale and Mustapha (2000), stated that some essential oils are highly lipophilic and therefore have the ability to penetrate the curticle of the insect or mite and that fatty vegetable oils kills insects by flooding their spiracles thus causing asphyxiation. Ofuya, (2002) used different essential oils to protect cowpeas and reported that oils extracted were potent in protecting stored cowpea seeds against infestation and damage by *C. maculatus.* According to his report, adult weevils are rapidly killed and oviposition and subsequent adult emergence may be completely prevented. Some researchers have proved the potentials in the use of neem oil to mitigate the deleterious effects of bean weevil attack on cowpea. Neem kernel extract of 1.69% w/w applied to the cowpea were effective in keeping the bruchids from developing (Lale and Mustapha, 2000). However, its usage has been faced with some challenges especially the problems of foul sulfurous smell and bitter taste (Ojiako and Kayode, 2014) besides the final input cost involved.

There have also been controversies on minimum effective ratios of the oil admixture that can effectively control the bruchids. Ilesanmi and Gunjuola, (2010), tried the following concentrations, 0.5 ml, 1.0 ml and 1.5 ml neem oil/200 g cowpea grains to check their efficacy on bruchids control and reported that the higher the dosage the higher the protection of grains. This work therefore seeks to assay the potency of Palm Kernel oil as a cheap adjunct to neem oil for the control of cowpea bruchid as a panacea for the foul sulfurous odour, bitter taste and high cost of neem oil when used alone. The objectives therefore were: 1) To evaluate the effect of neem oil and palm kernel oil (PKO) extract in the control of *Callosobruchus maculatus* infestation on cowpea and 2) To determine the best combination of Neem and palm kernel oils that will be most effective in the control of cowpea bruchid in stores.

MATERIALS AND METHODS

Location

The experiment was carried out at the Department of Crop Science Teaching and Research laboratory, University of Nigeria, Nsukka ($06^0$52ˈN, $07^0$24ˈE; 447.26 m asl) from February to August 2019.

Source and Preparation of Material

Local, untreated iron bean variety (*Phaseolus vulgaris*) were sourced from the grain reserve bank of the Department of Crop Science University of Nigeria, Nsukka, Enugu state Nigeria. The grains were handpicked to remove damaged ones and contaminants. The selected grains were placed inside polyethylene bags and fumigated against incipient cowpea weevils with phostoxin tablets at 0.83 mg /50 g cowpea. The tablet was sealed in a perforated paper with ten holes and

ISSN: 2814-0508

placed inside the polythene bag containing the grains. The fumigant was left in the cowpea grain for 3 days. The grains were later exposed for 48 hours to ensure that the phostoxin gas was completely removed.

Neem and palm kernel oil

Technical grade processed neem oil (100 ml) was purchased from a processing company (Company name) at Gudu district, Abuja, Nigeria. Cold pressed technical grade palm oil was also procured from Ugo-grade Technical Company Emene, Enugu, Enugu State, Nigeria. These were stored properly in a cool dry place at a temperature of ± 5 ^{0}C until used.

Insect culture

Adult *Callosobruchus maculatus* were collected from naturally infested stored cowpea from Nsukka main market. Clean cowpea seeds (250 g) were weighed out into plastic breeding containers and adult bruchids were introduced into the container and kept under ambient temperature (30 °C ± 2 °C) and relative humidity (75% ± 5%). Each of the containers had 20 perforations which were covered with muslin cloth to ensure proper aeration and prevent escape of weevils. The grains and bruchids were allowed to stay until emergence of new bruchids which were used for the experiment.

The sexes of freshly emerged bruchids were determined by examining the elytral pattern (Uzuegbu, 2005). The females are usually dark coloured and possess four elytral spots; while the males are pale brown and less distinctly spotted. Furthermore, males have comparatively shorter abdomen and the dorsal side of the terminal segment is sharply curved downwards. In contrast, the females have comparatively longer abdomen and the dorsal side of the terminal segment is only slightly bent downwards.

Preparation of Test Materials

Neem oil (N) and palm kernel oil (PKO) were measured out as follows; Neem oil (0 ml, 1.0 ml, 2.0 mls), PKO (0 ml, 1.0 ml, 2.0 mls), Neem and PKO were also mixed in the ratio of 1N: 1P, 1N: 2P and 1N: 3P. Each mixture was also measured out at the same rate (0 ml, 1.0 ml, 2.0 mls). Phostoxin was applied at the recommended rate of 83 mg/50 g cowpea. The treatments were represented as follows:

N_0P_0 = No neem, No PKO

N_1 = Neem at 1.0 ml

N_2 = Neem at 2.0 ml

1N:1P_1 = 10 ml Neem + 10 ml PKO at 1.0 ml

1N: 1P_2 = 10 ml Neem + 10 ml PKO at 2.0 ml

1N: 2P_1 = 10 ml Neem + 20 ml PKO at 1.0 ml

1N:2P_2 = 10 ml Neem + 20 ml PKO at 2.0 ml

1N:3P_1 = 10 ml Neem + 30 ml PKO at 1.0 ml

1N: 3P_2 = 10 ml Neem + 30 ml PKO at 2.0 ml

P_1 = PKO at 1.0 ml

P_2 = PKO at 2.0 ml

P_t= Phostoxin at 0.2 g/kg cowpea grains.

Bioassay

Fifty gram (50 g) each of disinfected cowpea grains were weighed into 12 perforated plastic containers (500 mls) to which the different appropriate treatments were applied with a syringe. The mixture was shaken thoroughly and laid out on a laboratory bench in a completely randomized design manner with three replications. Ten adult weevils comprising five males and five female bruchids were selected and introduced into each container and the containers were left undisturbed until observation started 24th hour after treatment.

Data collection

i. Mortality count of adult beetle taken at 24 hours, 48 hours and 72 hours after infestation (dead insects were confirmed by poking with office pin).

ii. Number of eggs/ seeds on the 7th day after infestation (this was taken on 20 randomly selected grains).

iii. Number of seeds with eggs per plate (taken on the 7th day of infestation)

iv. Number of emerged adults (dead and alive) on the 1st, 2nd, 3rd week and on the 7th days from the first emergence.

v. Number of emergence holes per grain (taken on 20 randomly selected grains on the 7th day from 1st emergence)

vi. Number of grains with hole. (taken as in number v above)

From the data collected the following calculations were made.

a. $\% \text{ mortality} = \dfrac{\text{Number of dead insects}}{\text{Total number of insect introduced}} \times \dfrac{100}{1}$

b. % Damage (PD) = $\frac{\text{Total number of sampled grains perforated}}{\text{Total number of sampled grains}} \times \frac{100}{1}$

c. Weevil perforation index (WPI) = $\frac{\text{Total number of treated grains perforated}}{\text{Total number of untreated grains perforated}} \times \frac{100}{1}$

A WPI exceeding 50% is regarded as enhancement of infestation by the weevil or a negative ability of the plant material or insecticide tested.

Data Analysis

Data obtained were subjected to analysis of variance (ANOVA) using Genstat System for Window Version 8. Differences amongst treatment means were separated using Fishers least significant difference (F-LSD).

RESULTS

Table 1 shows the mortality rate of *Callosobruchus maculates* at 24 hours, 48 hours and 72 hours after infestation respectively as influenced by different treatments and dosage rates. The treatments differed significantly ($p < 0.05$) in their effect on beetle mortality across the various periods (hours) evaluated except at 72 hours after infestation. It was observed that P_t (phostoxin) had significantly ($p < 0.05$) higher beetle mortality at 24 hours compared to N_0P_0 (0.75) which had the least mortality. Phostoxin (P_t) recorded similar mortality effect at 24 hours after infestation with N_2 and P_2 and which were statistically similar to 1N:1P_2 (1.18) and 1N:3P_2 (1.17). Grains treated with 1N:3P_1 had significantly ($p < 0.05$) higher beetle mortality at 48 hours than P_t, N_2, 1N:1P_2 and P_2 which had the same and least mortality value (0.71).

At 72 hours after infestation, there were no significant differences ($p < 0.05$) in beetle mortality across the various treatments but 1N:1P_1 recorded the highest mortality value, while P_t, N_2 and P_2 had the least mortality. The treatments however recorded significant differences in oviposition. Untreated grains N_0P_0 (1.76) had significantly ($p < 0.050$) higher oviposition count compared to P_t, N_2, 1N: 1P_2, 1N: 3P_2 and P_2, which is statistically similar to other treatments.

The emergence of the cowpea bruchids at 1st, 2nd, 3rd weeks after infestation and 7th day from the first emergence (Table 2) showed no significant difference on the 1st and 2nd week after infestation for all the treatments as there was no beetle emergence (0.00) from all the treatments. However, on the 3rd week after infestation, beetle emergence differed significantly ($p < 0.05$) among the treatments. No treatment (N_0P_0) recorded significantly higher emergence (2.04) than all other treatments. This was followed by P_1 (1.00) though it is statistically similar to the values recorded by the other treatments. On the 7th day from first emergence (DFE), there were significant difference ($p < 0.05$) among the treatments. The control N_0P_0 had significantly ($P < 0.05$) higher bruchid emergence (1.77) than the other treatments except N_1, 1N:1P_1, 1N:3$P_1$and P_1 with which it had statistically similar value.

Effect of treatments on percentage damage, number of adult emergence holes/seed, number of seeds with emergence holes and weevil perforation index at 10th week after infestation (Table 3) showed that untreated grains N_0P_0 (2.36) recorded significantly higher ($p < 0.05$) damage than other treated grains except grains treated with 1N:3P_1 (1.64) and N_1 (1.26) while the least values were obtained from those treated with P_2 and P_t (0.71).

On the number of perforations on grains, untreated grains (N_0P_0) showed significantly ($p < 0.05$) higher perforations (3.89) than all other treated grains. 1N: 3P_1 also recorded significantly ($p < 0.05$) higher number of perforations than P_t and P_2 which had the least number of perforations (0.71).

The number of grains with perforations were significantly higher with the untreated (N_0P_0) (2.84) than with other treated grains but did not differ significantly with $1N{:}3P_1$ (1.94) treated grains where P_t and P_2 treated grains recorded the least perforations (0.71). Weevil perforation index (WPI)

ISSN: 2814-0508

followed the same trend as the number of holes on grains and number of grains with holes. There were significant differences among the various treatments. N_0P_0 (31.49) had significantly ($p < 0.05$) higher WPI values which is similar to $1N:1P_1$ (24.19) while the treatment P_1 and P_2 showed the least index (12.20). The treatments $1N:1P_1$ and $1N:1P_2$ gave the same result for all the observations taken, they did not differ from each other (Table 3).

Data represent the square root transformed values.

DISCUSSION

The results obtained from this study showed that the two botanicals, neem oil and palm kernel oil extract and their admixtures can be effective in controlling *Callosobruchus maculatus* (cowpea weevil). As seen from the results, the highest rates of PKO and Neem (P_2 and N_2) exerted the highest mortalities within 24 hours of infestation. This corroborates the report of Emeasor *et al*. (2005) which states that botanical materials provide more effective control of insect pests at higher doses. Chukwulobe and Echezona (2014) also reported that 0.5 g and 1.0 g *Eugenia aromatic* powder were not as effective as 2.0 g in causing mortality of *Tribolium castaneum* in stored root/tuber chips. Results portrayed that the oil mixtures were effective in causing mortality within 24 hours of treatment.

This agreed with the reports of Grish (2008) that toxicity of these materials were expressed within 48 hrs of treatment. Makanjuola (1989) also reported that botanical extracts were toxic to *C. maculatus* within 48 hours of application. The minimum effective rate of neem oil, palm kernel oil extract and their admixtures in the control of the bruchids as seen in this study agreed with that earlier reported by Achio *et al*. (2012) that there was a direct relation between the active material concentration, rate of application and degree of lethal effectiveness. The performance of the botanical oil extracts did not differ with that of P_t (phostoxin) which was the standard positive control. This was a good indication that P_2 and N_2 can be good substitutes for P_t as storage protectants. These were similar to the effects of mixtures especially of $1N:2P_2$ and $1N:3P_2$. The result portrayed by these mixture levels may have been as a result of proper coverage of the grains by the oil extract at that quantity. As expected, however, the least mortality levels at 24 hours was observed in the negative control (no treatment). This agreed with the report of Adebola and Yusuf, (2016).

Mixtures applied at 1ml however had mortality values comparable to the no treatment control.

The effect of treatment on emergence of bruchids at first, second and third weeks of infestation and sevent day from the first emergence showed greater weevil emergence from the no treatment (control) grains. This was however expected as there was no protectant administered on the grains. Emergence started in the control plate on the third week after infestation and it was highest throughout the period of observation. Emergence was not observed at all from P_t, P_2, N_2, $1N:1P_2$, $1N:2P_1$, $1N:2P_2$, $1N:3P_2$. All these treatments totally suppressed beetle emergence from the treated plates. This could be as a result of the larger volumes of the oil to cause asphyxiation by flooding the spiracles, thereby causing death of adult insects, their eggs, larvae and pupae. This is in agreement with the report of Ofuya (2002), Lale and Mustapha, (2000).

On percentage damaged cowpea grains and weevil perforation index (WPI), P_t and P_2 gave the highest protection to the grains. This was followed by $1N:1P_1$, $1N:1P_2$ and $1N:2P_1$ and $1N:2P_2$. This trend was same for the number of perforations, number of grains with perforations and the weevil perforation index. Lower doses of neem and PKO were not very efficient in rescuing the grains from beetle attack and subsequent damage. This corroborate reports by many researchers (Emeasor *et al*., (2005); Chukwulobe and Echezona (2014); Ravi and Gayatri (2007) et. c).

The effect of the different treatments showed different protective abilities of the botanical oils and their admixtures when applied to stored grains. Generally, grains stored with the botanical oils recorded more bruchids mortality, reduced oviposition rate, decreased number of emerged insects and less damaged grains (hence decreased WPI) than the control (N_0P_0).

All parts of the neem tree, *Azadiracta indica* are insecticidal although the seeds possess the largest concentrations of azadirachtin, a steroid; tetranortiterpenoid, and nimbidic acid which possess a wide range of biological activities (Biswas, 2002). The mode of action includes feeding and oviposition deterrence, growth impairment, repellency and toxic insecticidal effects against 400 to 500 insect species in at least10-13 orders (Debashri, 2012). The use of neem oil extracts in storage pest control have been well documented against *C. maculatus* on Bambara groundnut (Obeng, 2014), on cowpea (Maina, 2004) and other stored products, legumes, sorghum, maize, wheat, rice, etc.

CONCLUSION

The study is ongoing so more research should be encouraged to find out the palatability and viability of grains treated with the various admixtures that showed prospects as effective measures of control especially those that has produced results that are comparable with the synthetic chemical (phostoxin) in terms of control of cowpea bruchid, *Callosobruchus maculatus*. Based on the above results, therefore, the following admixtures $1N:1P_1$, $1N:1P_2$, $1N:2P_1$, and $1N:2P_2$, which are next in effectiveness to the sole PKO oil, Neem oil and Phostoxin should further be studied for adoption as storage protectants, especially for *Callosobruchus maculatus*. Further studies will also help to discover the best mixtures in their ratios that will reduce the foul odor and bitter taste associated with neem oil on the grains and their cost effectiveness. Since the use of Neem extracts has been proven to be economically effective, it can be a better choice for farmers in the preservation of stored bean grains. PKO at 2 ml/50 g can also be used as an effective sole control agent as it caused a high percentage mortality on the insect population and is not associated with bitter principles.

ABSTRACT

A fungicide, Jorkemil Plus, with active ingredients Cuprous oxide 62% and Metalaxyl-M 12% was evaluated for its efficacy in the management of black pod disease of cocoa caused by Phytophthora megakarya in Nigeria. The field trials were laid out and conducted on a Randomized Complete Block Design (RCBD) on F_3 Amazon cocoa variety at the Experimental Stations of Cocoa Research Institute of Nigeria (CRIN) at Onigambari (Oyo State), Owena (Ondo State) and Ajassor (Cross River State). This fungicide was applied on the flowers, cherelles and cocoa pods. The fungicide was tried at the experimental stations simultaneously as spray applications at twenty-one (21) days interval. The records on incidence of black pod and pod production were taken at the same interval. The percentage black pod disease incidence by Jorkemil Plus was significantly lower (0.00-7.14%) than that of the control (6.35-29.69%). Cocoa pod production on the targeted cocoa trees during the trial revealed that the application of Jorkemil Plus enhanced cocoa tree yield potential by 18.27-29.78% compared with the reference fungicide (16.00-22.84%).

Key words: Cocoa, Black pod, *Phytophthora,* Fungicide, Cuprous oxide, Metalaxyl-M

INTRODUCTION

Cocoa is a highly prized commodity crop with its beans being a major export commodity for several countries in West Africa (WCF, 2014a; Abbott, 2013; ECA, 2013). Although the crop is native to the upper Amazon region of America, it is cultivated in Central and South America, Southeast Asia and Central and West Africa (WCF, 2014a; 2014b; ICCO, 2010). Cocoa is grown widely in the tropics, specifically in the tropical belt, within 15-20 degrees North and South of the equator (WCF, 2014b). The natural habitat of the cocoa tree is in the lower storey of the wet humid tropics and evergreen rainforest (ICCO, 2013; Orwa *et al*., 2009).

Production of cocoa is constrained everywhere it is cultivated. Among these are ageing trees, declining soil fertility and most especially, pests and diseases. In West and Central Africa, diseases are responsible for the majority of the losses. Black pod disease account for a larger percentage of the losses. *Phytophthora palmivora*, a pan tropical species and *P. megakarya,* an aggressive and extremely destructive species, are responsible for black pod disease (Agbeniyi, *et al.,* 2014; Kolawole *et al.,* 2014; USDA, 2014; Akrofi *et al.,* 2012).

In Nigeria, *P. megakarya* is the predominant species, highly virulent and very destructive (Kolawole and Goss, 2016). In some cocoa growing agro-ecologies, it could cause total loss of cocoa pod if not controlled. It is controlled by cultural practices and application of fungicides, which are mostly copper and metalaxyl-based. The use of fungicides is very popular among farmers because of its quick and relatively effective action. Nevertheless, relying solely on chemical in the control of black pod diseases is not advised. The use of fungicides should be the last resort in the disease management approach (Poole and Arnaudin, 2014). Securing effective control of the disease through fungicide application in the field depends on disease pressure and effectiveness of the fungicide. Therefore, it is of necessity to evaluate fungicides for their effectiveness before usage on cocoa plantations. Cocoa Research Institute of Nigeria (CRIN) is the only government agency in Nigeria saddled with the responsibility to assess fungicides for use on cocoa. Thus, the objective of this work is to evaluate Jorkemil plus, a metalaxyl based fungicide, for its effectiveness in the control of black pod disease of cocoa.

MATERIALS AND METHODS

Trial location and experimental layout

The cocoa plantation for the field trials were the experimental stations of Cocoa Research Institute of Nigeria (CRIN) located at Onigambari (Oyo State), Owena (Ondo State) and Ajassor (Cross River State), Nigeria. The cocoa plantations at the trial stations were purposefully selected based on history of high incidence of black pod disease during main and light cocoa cropping seasons. The experimental plots for this trial comprised of F_3 Amazon cocoa varieties planted at 3.1m x 3.1m spacing and the experimental design was Randomized Complete Block Design (RCBD) with 3 blocks. The treatment plots were demarcated and comprised of 27 cocoa trees per block, separated by guard rows of untargeted cocoa trees. Each treatment was replicated in triplicates per block.

Spray Application

The field application of test fungicide (Cuprous oxide 62% + Metalaxyl-M 12%) was evaluated at concentrations of 30g/15L, 40g/15L and 50g/15L. The spray application was targeted at the flowers, cherrelles and pods on the cocoa trees. An established fungicide known to be very effective in management of black pod disease on cocoa was used as reference (positive control) for test fungicide, while the cocoa stands without fungicide application served as negative control. Five fungicide spraying applications at the early hours of the day were conducted at 21 days' interval between June and November. The trials were simultaneously conducted at the selected locations. Post-treatment records of black pod incidences, number of cherrelles and pod production were taken at regular intervals.

Data Analysis

All data obtained in these trials were subjected to analysis of variance (ANOVA). Means of the treatments were compared using Duncan Multiple Range Test (DMRT) at ($p \leq 0.05$).

RESULTS AND DISCUSSION

The post-treatment data obtained on incidences of black pod disease from the trial Stations showed that there was no significant difference ($p \leq 0.05$) in the management impact of the test fungicide (Jorkemil Plus) and the reference fungicide on black pod disease of cocoa (Table 1). However, there was a significant difference ($p<0.05$) between that of the test fungicide (0.00-7.14%) and the untreated control (6.35-29.69%). The test fungicide applied at 50g/15L was more effective in the management of cocoa black pod disease. Results of the field trial corroborate the earlier findings of Orisajo *et al.* (2011) which reported the efficacy of copper oxide and metalaxyl in the management of black pod disease of cocoa. However, field reports have shown that the most effective and widely used active ingredients against black pod disease are the copper and metalaxyl-based fungicides. Findings from the trial have also shown coherence with the field report, as cuprous oxide 62% +Metalaxyl-M 12% have proven to be very effective in the management of black pod disease.

There was a significant increase in pod production on the cacao plot treated with the test fungicide- Jorkemil Plus (at 30, 40 and 50g/15l water) in all trial locations compared with the untreated control (Table 2). The observed increase in pod production could be attributed to the efficacy of the test fungicide's active ingredients in suppressing black pod incidence on the trial plot. This in turn permitted the expression of the inherent yield potentials of the cocoa trees treated with cuprous oxide and metalaxyl based fungicides such as Jorkemil Plus. The improvement on cocoa pod yield observed is similar to earlier study of Khan *et al*. (2006) which reported yield increase in cocoa occurring as a result of pesticide application. Norgrove (2007) also reported a 60% increase in yield of cocoa pod due to the application of fungicides.

CONCLUSION

Results obtained from this research justifies the recommendation of Jorkemil Plus as an effective fungicide for managing black pod disease of cocoa and for improving pod production, thereby making cocoa business more profitable to the farmers.

ABSTRACT

Cabbage (Brassica olercea var. capitata) is an eminent vegetable crop that is an important part of human diet all over the world. It forms a major source of vitamins and fibre that is taken in form of vegetables. The potential production of cabbage is mainly restricted by leaf spot disease caused by fungal pathogen. This disease is prevalent in all parts of the tropics where these crucifers are being produced. This makes farmers use fungicides indiscriminately for the management of pathogens, thereby endangering the lives of humans and also causing environmental pollution. Because of this injudicious use, the profits made by farmers do not commiserate with the expenses made through the procurement of fungicides thereby bringing down farmers' profits. An experiment was carried out to find the potency of three fungicides of varied chemistry and different concentrations against mycelia growth of Alternaria brassicicola under in-vitro condition. It was found that Mancozeb 630g/kg + Carbendazim 120g/kg (Green force) and Mancozeb 80%WP (Z- force) completely inhibited the mycelia growth at 400ppm. Thus it was concluded that these two fungicides could be used in field conditions for the management of Alternaria leaf spot at the same concentration, in a sequential manner to avoid environmental pollution and resistance development in the pathogen alongside with increasing the farmers' income.

INTRODUCTION

Biotic and abiotic factors are the major causal agents of plant diseases. These diseases play a vital role in the decline of products in agriculture. Apart from biotic and abiotic factors, genetic abnormalities also contribute to these declines. Among the biotic factors are fungi, bacteria, viruses, viriods, phytoplasmas, nematodes, parasitic higher plants and protozoans (Agrious, 2005). Gonzalez-Fernandez and Jorrin- Novo (2010) reported that among the plant pathogens that poses serious threat to Agricultural production; the phytopathogenic fungi are the most prominent parasitic organisms as compared to others. Ong (2011) reported also that approximately the presence of approximately 20,000 fungal species of plant pathogen and about 85% of these species are highly pathogenic. They are known to decrease yield worldwide (Boyraz ans Ozcan 2006). In southern Nigeria, crops are frequently infected by pathogens especially fungi due to the weather condition of the region. This attack by these pathogens causes both loss of yield in quality and quantity. Cruciferous vegetables are severely attacked by different species of Alternaria which may be either *A. brassicicola* or *A. brassicacea* or even other species of Alternaria. These pathogens cause leaf spot of these vegetables that belongs to the brassica family. Application of commercial fungicides remains the most convenient and predominant way for disease control. Their use has made it feasible for crop yield enhancement. The efficacy of fungicides is influenced by many biological and environmental factors that directly act on the metabolic activities of the fungal cells (Reinprecht, 2010). Indiscriminate application by farmers who do not have prior knowledge of the content of the fungicides and its application strategies also pose a lot of danger to the consumers and also environment. Also, in some cases, the critical concentration is not effective long-term as the fungi become resistant to those fungicides. The objective of this research was to check the efficacy of different concentrations of fungicides against *Alternaria sp*, the cause of leaf spot of cabbage.

MATERIALS AND METHODS

The vegetable was grown at the department of Crop Science teaching and research farm, Department of Crop Science, University of Nigeria, Nsukka. The basic agronomic practices for the propagation of these vegetables were followed. The heads of infected vegetable (Cabbage) was collected from the field and kept in paper bags. The sample was surface sterilized with 5% Sodium Hypochlorite (NaOCl) solution. Distilled water was used to wash the sample thoroughly for five times. Small pieces of the heads were cut, containing nearly half an infected portion and half healthy section. They were placed on potato dextrose agar (PDA) medium containing streptomycin to avoid contamination by bacteria. Incubation of the plated was carried out at 28 $^oC\pm1^oC$ for one week at 12-hour dark/light photo period (Meena *et al*. 2017). Single spore Isolation technique was used to purify the isolated pathogen culture. It was maintained in PDA slants for future investigations.

Identification of the pathogens

The isolated fungal culture was identified following the conventional taxonomic methods which included the characteristics of the colony and the spores. *Alternaria spp* was identified. The conidia were harvested from the border of isolated culture and placed on the microscopic slide having a drop of lactophenol solution to study the spore characteristics. Checking was done regularly at 24-hours interval for their colony characteristics. The identification was carried out on the basis of description given by the phytopathogen in different manuals and books (Barneth and Hunter, 1998; Gillman and Joseph, 1998).

The pathogenicity test

The identified pathogen isolate was tested for its pathogenicity on healthy vegetables under study to establish its pathogenic nature as per Koch’s postulates. The seed of the vegetable was taken and surface sterilized with 5% Sodium hypochlorite solution and washed thoroughly with distilled water, sown and allowed to grow for six weeks in a bag filled with sterilized top soil. The spore suspension of the identified Alternaria isolated was prepared at 2 x 10^6 colony forming unit (CFU) per milliliter and sprayed on the six week old vegetables. The inoculated vegetable was covered with transparent polythene in order to maintain humidity. Control vegetable was sprayed with distilled water. The symptoms development was recorded at 2, 4, 6, an 8 days after inoculation (DAI). Samples were isolated from the inoculated vegetables and compared with the original culture.

***In-vitro* evaluation of the fungicides against the fungal pathogen**

This experiment was laid out using completely randomized design (CRD) in the Department of crop science Plant pathology laboratory, replicated three times. Three fungicides were evaluated, viz- mancozeb 80%, mancozeb 630g/kg +carbendazim and Azoxystrobin 200g/l + difeconazole 125/l (Z-Force, Green Force and Fungicare respectively) to ascertain their ability to control the pathogen by poisoned food technique (Schmitz, 1930). Amendment of the P.D.A was done on all fungicides with 100, 200, 300, 400 and 500 ppm along with the control. They were paired into sterilized Petri plate and kept for solidification. A seven-day old pure culture of *Alternaria brassicicola* isolate was used for inoculation and 5mm discs were placed in the centre of each plate containing the fungicides along with the control. All the treatments were replicated 3times and they are kept at 28°C ± 1°C sealed with paraffin wax strips. Colony growths in each treatment were recorded 24 hourly until the plate got completely covered with the fungus. Inhibition percentage in the fungicide treatments were calculated over the control by using the formula below.

$$Percentage\ inhibition = \frac{X-Y}{X} X \frac{100}{1}$$

Where X= colony growth in control.

Y= colony growth in fungicide treatment.

Arcsine square root was used to transform the data collected before data analysis

Data analysis

Data collected were subjected to analysis of variance (ANOVA) using GenStat 10th edition release statistical software. Mean separation was done using Fishers least significance test at 5% probability level as described by Obi (2002).

RESULTS

Isolation and identification of pathogen

The isolated fungi formed a dark mycelia colony in appearance due to pigmentation. The colony texture is smooth. The isolated fungi produced hyphae that was initially hyaline which later converted to dark colour septate and branched mycelium. The conidiophores arise singly and bunchy to form vegetative hyphae. The coniodiophore is dark, geniculate and have a swollen base. The basal cell of the conidia is swollen and tapered towards the apex. The morphological descriptions of the colony and conidia of the phytopathogen validates the description given by (Barneth and Hunter, 1998) about *Alternaria brassicicola.*

ISSN: 2814-0508

Healthy cabbage

Infected cabbage

Pathogenicity test.

The initial symptoms of the inoculated cabbage were observed three days after it was transplanted. The symptoms appeared on the lower leaves and at 8WAT (weeks after transplanting), when the cabbage has started forming head, the dark spot appeared on the cabbage head, the spot coalesced and enlarge rapidly. The fungus was re-isolated using the symptomatic leaves of the inoculated plants. It showed almost the same characteristics to the original culture, thus completing all the criteria of Koch's postulates and confirming the pathogenicity of the isolated *Alternaria Brassicicola* culture to be pathogenic on cabbages.

***In-vitro* evaluation of different concentrations of fungicides against the fungal pathogen**

The in-vitro evaluation of fungicare (Azoxystrobin 200g/l + Difeconazole 125g/l), Green force (Mancozeb 630g/kg + Carbendazim 120g/kg) and Z-force (Mancozeb 80% WP) at 100, 200, 300, 400 and 500 ppm showed that they could all significantly inhibit the growth of *Alternaria brassicicola* Table 2. At 100, 200, and 300 ppm concentrations, Green force showed the maximum inhibition of mycelia growth while Fungicare recorded the minimum inhibition of the mycelia growth. At 400 and 500 ppm concentrations, Green force and Z-force showed total inhibition of mycelia growth followed by fungicare that recorded the 91.29 % and 93.06 % respectively. This proves that all the fungicides possess inhibitory actions against Alternaria brassicicola as all the results are statistically significant. Moreover, Green force and Z-force proves to be more effective against the phyto pathogen as they can inhibit the growth of mycelia at 400 and 500 ppm concentrations.

DISCUSSION

In this study, the different concentrations of the fungicides used had an inhibitory effect on the mycelia growth of Alternaria leaf spot on cabbage. The fungicide that contains carbendazim and mancozeb had the most effect. However most of the fungicides used did not differ significantly as all of them showed that they can be used to control ALS in *in-vitro* conditions. A similar inhibitory action of Mancozeb and Carbendazim 50%WP was demonstrated by Kumar *et al*. (2017), Jong-hwan *et al*. (2017), Saha *et al*. (2018), and Rajeswari and Balasupramani (2020) on *Alternaria* leaf blight of tomato, ginseng, cabbage, and pigeon-pea, respectively.

CONCLUSION AND RECOMMENDATION

All the fungicides studied were effective in inhibiting the mycelia growth of the isolate. The 400 and 500 ppm concentration of both green force (Mancozeb + Carbendazim) and Z- Force (Mancozeb 80%WP) was more effective as it gives total inhibition at these concentrations. On the basis of these results, I recommend Mancozeb + Carbendazim) and Z-Force (Mancozeb 80%WP) for the *in vitro* control of *Alternaria brassicicola*, that cause leaf spot of cabbages. However, detailed research is needed to solve the long lasting problem for the farmers and also residual analysis is recommended for field trial to ascertain safe consumption for consumers.

ABSTRACT

Field studies was conducted during the 2018 and 2019 growing seasons at Bayero University Kano (BUK) (Latitude 11° 58.861' N and longitude 008° 25.155' E, altitude 449 m above sea level) and National Horticultural Research Institute (NIHORT). Located at Bagauda in Bebeji Local Government Area of Kano State (Latitude 11^0 33^{1}N and longitude 8^{0}23^{1}E with altitude of 481m above sea level) in the Sudan Savannah of Nigeria in order to determine the Phyto-sociological attributes of arable weeds of the area drylands. Random quadrat method was adopted for the phytosociological studies. In each location, sixty-four plot were randomly selected. In each experimental locations quadrats of 4 m2 size were laid down and hence sum of 124 quadrats were randomly thrown for each location. Within each quadrat area, weeds were identified, counted and weed cover scores were recorded. Weeds were cut at ground level, fresh and dry weights were determined. Pennissetum violaccum, Paspalum tremula, Cassia occidentalis, Ipomea specie, Cynodon dactylon, Cyperus retundus, Acanthuspermum hispidum, and Sida acuta, were the most dominant species in the drylands of Bagauda and BUK that have 5% and above compared to either weeds specie in the locations. Weed density, weed cover scores as well as fresh and dry weight of weed samples from Bagauda were observed to be higher than that of BUK. Morphological characteristics of those weed spp found in Bagauda and BUK were aggressive and can easily dominate the area if not control and lead to low yield of sunflower and other related crops. The study suggested that there is strong need to start an Integrated Biological weed management in the study areas.

Keyword: phyto-sociological attributes, weeds, relative density, relative frequency, Summed ratio, Specie and Quadrant

INTRODUCTION

Sunflower (*Helianthus annuus* L.) belongs to the family Asteraceae order Asterales. It is an important oilseed crop which ranks third after soybean and groundnut as a source of edible oil in the world (Oyinlola *et al*., 2010). The crop originated in North America (anonymous, 2016). Today it has become naturalized in many locations of the tropics and is widely cultivated in Africa. *Helianthus annuus* was introduced into Africa through colonial masters and it was widely cultivated in South Africa. Although statistical data on production level and hectares in Nigeria are not available (Adebayo *et al* 2010), grain yield above 1 t ha-1 has been reported depending on cultivars planted (Olowe *et al* 2005). However, due to its potential and high oil content its cultivation is now rapidly expanding in other agro-ecological zones of Nigeria.

Weed control had been one of the fundamental problems of crop production (Farooq *et al.,* 2008). Weeds left unmanaged caused massive yield losses in sunflower field crops (Jabran *et al.,* 2008 *and Jabran et al.,* 2010). Yield losses in major crops have been reported by several authors. In Nigeria half of the effort devoted to crop production is spent on weed control. Other problems associated with weeds in agriculture include: reduced crop quality by contaminating the commodity interference with harvest; serve as hosts for crop diseases or provide shelter for insects to overwinter, reduced crop quality by contaminating the commodity. Weed drastically reduced sunflower yield to about 70 to 80 percent lost (Anonymous, 1998). Research studies have demonstrated that there was up to 80% yield loss in okra as a result of weed infestation (Aladesanwa and Adejobi, 2007).

MATERIAL AND METHODS

Field studies were conducted during the 2018 and 2019 rainy seasons at Bayero University Kano (BUK) (Latitude 11° 58.861' N and longitude 008° 25.155' E, altitude 449 m above sea level) and National Horticultural Research Institute (NIHORT) at Bagauda in Bebeji Local Government Area of Kano State (Latitude 11^0 33^1 N and longitude 8^0 23^1 E with altitude of 481m above sea level) in the Sudan Savannah of Nigeria. The treatments consisted of three plant spacing (30 cm x 75 cm, 65 cm x 75 cm and 70 cm x 75 cm) and eight weed control methods. These were factorially combined and laid out in split plot design and replicated three times. Spacing was the main plot and weed control methods sub plot. Plot size was 6m × 7m long consisting of six ridges with spacing of 75cm between rows and Alley ways of 1.0 m was allowed between the plots and 2 m between the replicates. A 1 m by 1 m quadrant was randomly thrown in different plots to extrapolate and determine the relative density, relative frequency and summed ratio of weeds present at Bagauda and BUK in 2018 and 2019 rainy season.

Phytosociological Attributes of Weed

The phytosociological attributes of weeds such as relative frequency, relative density and Summed domance ratio were calculated according to the principles of Curtis and McIntosh (1950). The following formulae was used to calculate the relevant phytosociological attributes of weeds were.

$$Relative\ frequency\ = \frac{frequency\ of\ individual\ weed\ specie}{Total\ frequency\ of\ all\ specie} X\ 100$$

$$Relative\ density\ = \frac{density\ of\ individual\ weed\ specie}{Total\ density\ of\ all\ specie} X\ 100$$

$$Summed\ Dormance\ Ratio\ = \frac{relative\ frequency + relative\ density}{2} X\ 100$$

RESULTS AND DISCUSSIONS

Phytosociological Attributes of Weed Species Associated with sunflower

Weed Specie Composition

The results of the study show that, the weed species composition consisted of different species of broad leaved, narrow leaved and sedges in association with the production of sunflower in 2018 and 2019 rainy seasons in the experimental sites are presented in Table 1. The results indicated a total number of thirty-five (35) weed species associated with Sunflower at Bagauda and BUK.

This is in line with Weber et al. (1995) reported 74 weed species in intensified cerealbased cropping systems in northern Guinea savanna of Nigeria under terrestrial condition. Twenty-five (25) species are broad leaved appeared in all the years at both locations. The most dominant species among the broad leaved weeds across the years include *Acanthuspermum hispidum, Amaranthus spinusis, Cassia occidentalis, Euphorbia heterophylla L., Evolvulus alsinoids, Ipomea aquatica, Ipomea furera, Vernonia cinerei, Minosa invisa, and Sida acuta appeared* in both years at both locations. Lado et al., (2016) reported in his results indicated that only three narrow leaved species (Cynodon dactylon, Sorghum halepans and Typha species) consistently appeared in all locations in both seasons indicating their wide spread. These weeds were dominant may be due to rainfall and favorable climatic condition that govern their production in both areas. Farmers has to control weeds to maximize the yield because weeds reduced yield to reasonable percentage. Weeds left unmanaged caused massive yield losses in sunflower field crops (Jabran *et al.,* 2008 *and Jabran et al.,* 2010). This was in line with Das, (2011) and Awodoyin and Akande, (2014) that reported weed is any plant, native or non-native that interferes with crop by competing with crops for limited resources in agroecosystems and has the habit of encroaching where it is not wanted. Weeds develop rapidly and are able to self-pollinate, disperse widely and tolerate wide range of environmental conditions (Akubundu, 1987; Frick and Johnson, 2012). There were 12 narrow leaved associated with sunflower production. The most dominant species are *Cynodon dactylon, Panacum laxum, Paspalum tremula, Pennissetum violaccum,* and *Schwenekia Americana* in 2018 at Bagauda.

Lado et al., (2016) reported that Ten (10) broadleafspecies constituting 42% of the total weed species (Ageratum conyzoides, Azolla pinnata, Eichornia natans, *Hydrilla* speciesIpomea asorifolia, Melochia corchorifolia, Nymphaea lotus, *Phyllanthus* amarus, *Polygonum salicifolium* and *Portulaca oleraceae).* Three sedges are dominant weed species across the experimental years and at both locations. They include *Cyperus ferosta, Cyperus retundus and Kylinga squamulata* in 2018 and 2019 at Bagauda and BUK respectively. Other weed species like *Leunotis nepetipollia* appeared only at BUK in 2018 and 2019 while *Tepprosia linearis* and *Oldenlandia carymbosa* appeared only at Bagauda in 2018 rainy season.

Relative Frequency

The relative frequency of weed species associated with sunflower at Bagauda and BUK in 2018 and 2019 was presented in Table 2. In 2018 at Bagauda only 4 species recorded relative density of 5 % and above. Among them *Pennissetum violaccum* and *Paspalum tremula* had the highest frequency followed by *Metrocarpus villosus, Evolvulus alsinoids and Cassia occidentalis.* However, in 2019 season in this location up to 7 weed species recorded the relative frequency of 5 % and above. Among which *Pennissetum violaccum* had the highest relative frequency followed by *Paspalum tremula, Cassia occidentalis, Ipomea aquatica, Ipomea furera, Cynodon dactylon, Cyperus retundus* and *Cyperus ferosta*. About 22 weeds species recorded less than 1 % relative frequency in 2018 while 11 species recorded less than 1 % relative frequency in 2019 in this location. However, 6 weed species appeared in 2018 but absent in 2019 they include *Crotalaria macrocalyx, Imperita cylindrica, Monechmi citistum, Tepprosia linearis, Hydrolea palustris* and *Mariscus longibracteautus*. While at BUK only 5 weed species appeared in 2018 but absent in 2019.

TOTALS	100	100	100	100

They include *Euphorbia heterophylla, Imperita cylindrica, Hydrolea palustris, Mariscus longibracteautus, Phyllatum amarus.* 24 weed species appeared in all the experimental years and at both locations such as *Acanthuspermum hispidum, Amaranthus spinusis, Asphilia africa, Cassia occidentalis, Cleom viscosa L, Digitaria horizontalis, Evolvulus alsinoids*, *Ipomea aquatica, Ipomea furera, Vernonia cinerei, Metrocarpus villosus, Minosa invisa, Senna abtusifolia L, Sida acuta, Tridex procumbens L, Cynodon dactylon, Eragrostic arrovirens L., Leucas matinenicensis, Panacum laxum, Paspalum tremula, Pennissetum violaccum, Schwenekia Americana, Cyperus ferosta, Cyperus retundus and Kylinga squamulata.*

The relative frequency of weed specie composition at BUK in 2018 and 2019 as presented in Table 2. In 2018 only 7 specie recorded the relative frequency of 5 % and above. These are *Evolvulus alsinoids, Leunotis nepetipollia, Leucas matinenicensis, Paspalum tremula, Pennissetum violaccum* and *Kylinga squamulata.* In 2019 at the

ISSN: 2814-0508

same location 5 weed specie recorded relative frequency of 5 % and above. These are *Ipomea furera, Metrocarpus villosus, Sida acuta, Paspalum tremula, Pennissetum violaccum and Cyperus ferosta.*12 and 11 weed specie recorded less than 1 % of relative frequency in 2018 and 2019 season respectively in this location.

Relative Density

The relative density of weed species at Bagauda and BUK in 2018 and 2019 season was presented in Table 3. In 2018 at Bagauda *Pennissetum violaccum* had the highest relative density followed by *Paspalum tremula*. However, in same location in 2019 only four weed specie recorded 5 % and above. This include *Pennissetum violaccum, Paspalum tremula, Metrocarpus villosus* and *Evolvulus alsinoids* however in 2019 eight weed species recorded 5 % and above of relative density. They are *Acanthuspermum hispidum, Cassia occidentalis, Ipomea aquatica, Sida acuta, Cynodon dactylon, Paspalum tremula, Pennissetum violaccum* and *Cyperus retundus*. About 24 weed species recorded less than 1 % of relative density in 2018 while 9 specie record less than 1 % relative density in 2019. Only 6 weed species appeared in 2018 and they were absent in 2019 season in this location. They are *Crotalaria macrocalyx, Imperita cylindrica, Monechmi citistum, Tepprosia linearis, Hydrolea palustris and Mariscus longibracteautus.*

The relative density of weed species associated with sunflower at BUK in 2018 and 2019 season was presented in Table 3. At BUK in 2018 only 6 specie had relative density of 5 % and above. This included *Cassia occidentalis, Evolvulus alsinoids, Vernonia cinerei, Metrocarpus villosus, Leunotis nepetipollia, Paspalum tremula* and. In 2019 up to 10 weed species had relative density of 5 % and above in this location. They include *Acanthuspermum hispidum, cassia occidentalis, Sida acuta, Cynodon dactylon, Eragrostic arrovirens, Paspalum tremula, Pennissetum violaccum, Cyperus ferosta, Cyperus retundus and Kylinga squamulata* 17 and 10 weed species had relative density of less than 1 % in 2018 and 2019 season respectively.

Summed Dormancy Ratio

The summed dormancy ratio of weed specie at Bagauda and in 2018 and 2019 season was presented in Table 4. In 2018 season at Bagauda only 5 species recorded summed dormancy ratio of 5 % and above. Among them *Paspalum tremula* had the highest followed by *Pennissetum violaccum and Metrocarpus villosus.* However, in 2019 season in this location up to 12 weed species recorded summed dormancy ratio of 5 % and above. Among which *Paspalum tremula* recorded the highest followed by *Metrocarpus villosus, Pennissetum violaccum, Cyperus ferosta, Schwenekia Americana, Kylinga squamulata, Cyperus retundus, Imperita cylindrica, Evolvulus alsinoids, Cleom viscosa, Monechmi citistum and Acanthuspermum hispidum.* About 13 weed species recorded summed ratio dormancy of less than 1 % in 2018 while 3 weed species recorded less than 1 % summed ratio in 2019 in this location. However, there were species that were appeared in 2018 and were absent in 2019.

Table 4 presented the Summed Dormancy Ratio Associated with Weed at BUK in 2018 wet season in this location. 8 species recorded summed dormancy ratio of 5 % and above. Among these are *Pennissetum violaccum, Paspalum tremula, Kylinga squamulata, Cyperus retundus, Cyperus ferosta, Metrocarpus villosus, Leunotis nepetipollia, and Evolvulus alsinoids.* However, in 2019 at the same location 13 weed species recorded the summed dormancy ratio of 5 % and above. They include *Pennissetum violaccum, Paspalum tremula, Kylinga squamulata, Cyperus retundus, Cyperus ferosta*, *Evolvulus alsinoids*, *Evolvulus alsinoids Digitaria horizontalis, Cassia occidentalis and Acanthuspermum hispidum.* 11 and 6 weed species recorded the summed density ratio of less than 1 % in 2018 and 2019 season respectively.

CONCLUSION AND RECOMMENDATION

The results of the study showed that weed drastically effect horticultural crops thereby reducing yield, increased cost of production, hinder pest and diseases, reduced the value of the produced. *Pennissetum violaccum* and *Paspalum tremula* had the highest frequency, relative density and summed ratio followed by *Metrocarpus villosus, Evolvulus alsinoids and Cassia occidentalis.* Therefore, there is need to control these weeds through integrated weed control to burst horticultural crop production. It's recommended that if these weeds were control the lively hood of farmers would be increased.

ABSTRACT

This research was carried out in Nukkai River Basin (NRB) at the boundary between Ardo-kola and Jalingo local Government areas of Taraba state between 2014 and 2015. Nukkai river basin is naturally divided into four units by the Nukkai Bridge: the upper Nukkai (UN), lower Nukkai (LN) units in Jalingo local government (JLG) area and upper Kofai (UK) and lower Kofai (LK) units in Ardo-kola Local Government (ALG) area. The types of crops grown in each unit were examined, 3-4 farms randomly selected based on the types of crops served as the sampling units. A 1m X 1m quadrat was thrown randomly 3-4 times at about 20m intervals in each of the farms. Weed species within the 1m^2 quadrants were harvested, sorted and identified. Thirteen crop combinations were identified in the Nukkai River Basin of Taraba State. The frequency of occurrence of crops was in the order: Maize> Amaranthus> Rice> Groundnut, Pepper or Tomato> Sorrel> Sugar cane or Onion/Pepper/ Huckleberry> Cassava or Sweet Potato. Between the LGAs, the dominance of farms planted with cereals and root/tuber crops was higher in ALG than JLG, while JLG has more farms cultivating vegetables and other crops (sugarcane and groundnut). An indication that nutrient security potential might be higher in JLG than ALG. Across the units and LGAs, the order Vegetables (43.6%) > Cereals (41.9%) >others (11.3%) > Root/tubers (3.2%) was observed. Seven grasses, four broadleaf and two sedges were identified in the whole of the river basin. Digitaria milanjiana, Portulaca oleracea, Ageratum houstonianum, Ornithogalum caudatum, Echinochloa stagnina and Physalis angulata contributed 77.4% to the weed matrix in ALG. Digitaria milanjiana, Portulaca oleracea, Ageratum houstonianum, Setaria verticillate, Setaria barbata and Physalis angulata contributed 83.0% to the weed matrix in JLG. These weeds need to be monitored for higher productivity of vegetables and enhanced nutrient security in the study area.

Key words: Vegetables, Nutrient security, weed flora, Fadama

INTRODUCTION

Weeds species are the most important, yet most under-estimated of crop pest (Chauhan, 2020). Weed is the most limiting and visible cause of yield loss and a major constrain in Fadama areas (Amare *et al*, 2000). Fadama lands are fertile, supports high biodiversity, reduce risk of crop failure and have more agricultural potential than the adjacent upland (Ingawa, 1998). This weed species, biology, diversity as well as control methods by farmers in Nukkai river basin need to be evaluated for enhanced productivity. In tropical Africa, weed constitutes the major problem in subsistence agriculture and is the major challenge that farmers are facing when growing their crops (Fadayomi, 1996).

Weed control is the dominant labour-demanding occupation of small holder farmers in semi-arid regions of Africa during the cropping season (Akobundu, 2011). Farmers invest large amounts of labour in weeding each season, approximately 35 to 70% of the total agricultural labour need, which limits labour supply for other livelihood operations for small holder farmers (Mashingaidze *et al*., 2019). No single weed management strategy have effectively controlled weed in any cropping system (Ogbimi, 1998). Managing weeds without adequate knowledge of their biology, life cycle, characteristics will limit sustainable control, hence this study surveyed weed flora associated with crops cultivated in the Fadama.

MATERIALS AND METHODS

This research was carried out in Nukkai River Basin (NRB) at the boundary between Ardo-kola and Jalingo local government areas of Taraba state. Taraba state is roughly between latitude $6^0 30"$ – $9^0 36"$ north and longitude $9^0 10"$ – $11^0 50"$ east in north Eastern part of Nigeria. Taraba state have about 2.3 million people. (N.P.C, 2006 population census) inhabiting an estimated land area of about 54,428 km2. Adebayo (2010), divides Taraba into southern, central, northern zone where rain onset starts 16th March, 6th and 26th April respectively. About 75% of Tarabans are involved in farming.

The geological terrain of Jalingo local government is plain with rocky areas, while Ardo-kola is plain with little rocky areas. The climate is tropical, average annual temperature is 25.3°C, the average annual rainfall is 931 mm. (T.A.D.P, 2001). The area under study is broadly divided into four units, the upper and lower Nukkai units (JLG) and upper and lower Kofai units (Ardo-kola Local Government, (ALG) area. Nukkai river basin is naturally divided into four units by the Nukkai Bridge. The four units are characterized by different types of crops grown in the area. About 3-4 farms randomly selected based on the types of crops served as the sampling units. A 1m X 1m quadrat was thrown randomly 3-4 times at about 20m interval in each of the farms. Weed species within the $1m^2$ quadrants were harvested, sorted and identified.

RESULTS AND DISCUSSION

Cropping System of Nukkai River Basin (NRB)

Table 1 shows the thirteen crop combinations identified in Nukkai River Basin of Taraba State. The frequency of occurrence was in the other, Maize> Amaranthus> Rice> Groundnut, Pepper or Tomato> Sorrel> Sugar cane or Onion/Pepper/Huckleberry> Cassava or Sweet Potato. Maize, amaranth and followed by rice were the most dominant crops cultivated in the area (Michael and Aliyu, 20l2). This is because of consumers' preference, and it is one of the major crop and vegetable cultivated in Taraba state. Maize is one of the world top crop, maize provide not only the fast food of Nigerian society breakfast cereals, sweet corn and popcorn but also the staple food for much of the world population in developing countries where it is used to make porridge, bread (Mijindadi and Adegbehnin, 1991). All round the world, maize grain is the basic livestock feed, and the crop can be cut while still green to make silage as a winter feed (Orthmann, 2005).

Within Ardokola Local Government (ALG) units of the river basin, two cereal crops, onion/pepper and amaranthus were cultivated in both lower kofai (LK) and upper kofai (UK) units. Sugarcane, Sorrel, Huckleberry and tomato were only found in LK while Groundnut, cassava, sweet potato, tomato/pepper mix were only cultivated in UK. Cereal and root/tuber crops were more dominant in UK than LK, while vegetables farms were more in LK than UK. Within Jalingo Local Government (JLG) there were one cereal (UN > LN), sugarcane/groundnut (UN <LN) and four vegetables (UN < LN).

Between the LGAs, the dominance of farms planted with cereals and root/tuber crops was higher in ALG than JLG, while JLG has more farms cultivating vegetables and other crops (sugarcane and groundnut). An indication that nutrient security potential might be higher in JLG than ALG. Across the units and LGAs, the order Vegetables (43.6%) > Cereals (41.9%) >others (11.3%) > Root/tubers (3.2%) was observed. Fadama is generally known for vegetable production in many places because of high and sustained moisture requirement and continuous demand during dry season. The assessment of the spread of farms indicated that maize and amaranthus occurred in all the four units and LGAs; Groundnut, sorrel and tomato in three units; rice and sugarcane in two units, while other crops were observed in only one unit. This reflected effective site selections, especially for rice/sugarcane in the lower units with possible higher moisture content and availability suitable for such crops. The root/tuber crops in the ALG justifies the siting of the cassava processing industry in Ardokola LGA and an oil extracting factory in Jalingo LGA.

Weed Flora

Table 2 shows the different types of weeds identified in all units under study. Seven grasses, four broadleaf and two sedges were identified in the whole of the river basin. In the UK, *Digitaria milanjiana and Ornithogalum caudatum* were the dominant weeds, followed by *Portulaca oleracea, Ageratum houstonianum, Physalis angulata and Setaria barbata*. However, in LK, *Digitaria milanjiana, Portulaca oleracea, Echinochloa stagnina, Ageratum houstonianum.* In the LGA, the order *Digitaria milanjiana, >Portulaca olerace,> Ageratum houstonianum/ Ornithogalum caudatum> Echinochloa stagnina, Physalis angulata> Rhynchospora corymbose/ Setaria barbata/ Heliotropium indicum> Sida cordifolia/ Setaria verticillate> Cynodon dactylon. Digitaria milanjiana, Portulaca oleracea, Ageratum houstonianum, Ornithogalum caudatum*, *Echinochloa stagnina and Physalis angulate* contributed 77.4% to the weed matrix in ALG.

Common purselane (*Portulaca oleracea)* was normally found in amaranthus, onion and sorrel plots (Loux and Berry, 1991). Common purselane is a broadleaf weed, and is normally found in wet areas such as Fadama areas and especially in some irrigated areas (Dowler, 1998). The weed species always do better in areas with continuous supply of water such as Fadama areas, river bands and or irrigated plots (Qureshi, 1989).

In UN, *Setaria verticillata* > *Digitaria milanjiana*> *Setaria barbatal Physalis angulate/ Ageratum houstonianum/ Echinochloa stagnina/ Portulaca oleracea*> *Cyperus iria* order was observed. In LN, the order *Digitaria milanjiana,>Portulaca oleracea/ Ageratum houstonianum* > *Sida cordifolia*> *Cyperus iria/ Setaria barbata/, Physalis angulatel Setaria verticillate*. The order *Digitaria milanjiana,>Portulaca oleracea/ Ageratum houstonianum/ Setaria verticillate* > *Setaria barbata/, Physalis angulate*> *Cyperus iria/ Echinochloa stagnina*. *Digitaria milanjiana, Portulaca oleracea, Ageratum houstonianum, Setaria verticillate, Setaria barbata* and *Physalis angulata* contributed 83.0% to the weed matrix in JLG.

Comparing weed flora between the two LGAs. The dominance of *Digitaria milanjiana*, *Portulaca oleracea,* and *Echinochloa stagnina* in ALG was higher than in JLG, whereas *Ageratum houstonianum, Setaria verticillate, Setaria barbata* and *Sida cordifolia* were more in JLG than ALG. Weeds that were peculiar to ALG alone include *Ornithogalum caudatum, Rhynchospora corymbose, Heliotropium indicum* and *Cynodon dactylon*. *Digitaria*, while *Cyperus iria wa*s found only in JLG units alone.

This trend reflected crop-weed association essentially and ecological requirements Bristly foxtail (*Setaria verticillate)* was the highest weed identified in upper Nukkai and it was normally found in Amaranth, onion, sorrel, pepper/tomato, and onion/pepper plots as reported by (Loux and Berry, 1991).

ISSN: 2814-0508

Bristly foxtail is a grass weed, and is normally found in wet areas such as Fadama areas and irrigated lands/areas (Akobundu and Agyakwa, 1998).

Common purselane identified in lower Nukkai was normally found in amaranths, onion and sorrel plots (Loux and Berry, 1991). Common purselane is a broadleaf weed, and is normally found in wet areas such as Fadama areas and especially in some irrigated areas (Dowler, 1998). Most of the weed Species identified are Fadama weeds or irrigated land weed species, they are always present in areas with much water (Akobundu and Agyakwa, 1998).

CONCLUSION AND RECOMMENDATION

Thirteen crop combinations were identified in the Nukkai River Basin of Taraba State. The frequency of occurrence of crops was in the order: Maize> Amaranthus> Rice> Groundnut, Pepper or Tomato> Sorrel> Sugar cane or Onion/Pepper/ Huckleberry> Cassava or Sweet Potato. Between the LGAs, the dominance of farms planted with cereals and root/tuber crops was higher in ALG than JLG, while JLG has more farms cultivating vegetables and other crops (sugarcane and groundnut). An indication that nutrient security potential might be higher in JLG than ALG. Across the units and LGAs, the order Vegetables (43.6%) > Cereals (41.9%) >others (11.3%) > Root/tubers (3.2%) was observed. Seven grasses, four broadleaf and two sedges were identified in the whole of the river basin. *Digitaria milanjiana, Portulaca oleracea, Ageratum houstonianum, Ornithogalum caudatum*, *Echinochloa stagnina and Physalis angulata* contributed 77.4% to the weed matrix in ALG. *Digitaria milanjiana, Portulaca oleracea, Ageratum houstonianum, Setaria verticillate, Setaria barbata* and *Physalis angulata* contributed 83.0% to the weed matrix in JLG. These weeds need to be monitored for higher productivity of vegetables and enhanced nutrient security in the study area.

ABSTRACT

Weed flora is a common problem in any crop field. For the better management of crop, understanding of weed vegetation is obligatory. Cocoa unfortunately is threatened by many constraints among which are weed infestation resulting in significant yield losses. Hence, the present study was aimed at documenting the weeds in cocoa varieties Tc1, Tc2 and F3 Amazon, predict weed growth characteristics in terms of densities, frequencies, importance value and diversities and, to use the predictions for selection of weed control measures that have some desired effects. Thus; a field experiment was conducted in June 2014 in two different agro-ecologies of southwest Nigeria viz: The Cocoa Research Institute of Nigeria (CRIN), Ibadan (Lat. 7° 10′ N, Long. 3° 52′ E,) representing dry forest and CRIN, Owena (7^0 11′ N, 5^0 01′ E) Sub - station, Ondo State, Nigeria representing wet forest. The experiment was a split plot in a Randomized Complete Block Design (RCBD) with three replications per treatment. The varieties (CRIN Tc-1, CRIN Tc-2 and F3 Amazon obtained from the headquarters of CRIN, Idi-Ayunre in Ibadan) were allocated to the main plot and weeding regime (WR) into sub-plots as: WR1. (weedy for 1 month + weeded after for 4 months), WR2. (weedy for 2 months + weeded after for 3 months); WR3. (weedy for 3 months + weeded after for 2 months); WR4. (weedy for 4 months + weeded after for 1 month); WR5.WF (weedfree throughout); WR6.WY (weedy throughout). Plantain was used to provide shade crop for the cocoa stands and was established a year before transplanting cocoa at a spacing of 3 x 3 m, (ditto for cocoa) and three stands of cocoa covering 3 x 6 m = (18 m^2) / treatment was used. Weeds were sampled once from one 50x50cm quadrate per sub-plot for each treatment. The data were analyzed by excel package of simple percentages and weed species diversity (H´) was computed from weed density, according to Pielou (1969). The results showed that: varieties Tc1, Tc2 and F3 has 54,56 and 62 weed types, higher weed flora diversity in WR1, distinctly widespread occurrence of C. odorata, general increase in weed occurrence across experimental sites caused by weed succession and adaptation patterns, dominance of C. odorata and widespread unappreciable weed RIV (≤10%) recorded across the locations. It was therefore concluded that, weed identification studies helps in knowing the existing weeds which can be a clue for their prevention and control, avoid early weed infestation at cocoa establishment, prevent local seeds and whole stem distribution of C. odorata with others like Aneilema aequinoctiale, Asystasia gangetica, Brachiaria deflexa, Digitaria horizontalis, Momordica charantia, Oplismenus burmanii, Sclerocarpus africanus from becoming invasive. Therefore, early weeding planning in cocoa plantations such that weeds don't get to a threshold level is important.

Key words: *Weeding regime (WR), Mean density (no./m^2), Frequency (%), Diversity (H^I)*

INTRODUCTION

No matter what definition is used, weeds are plants whose undesirable qualities outweigh their good points (Dwight, 2009). Certain characteristics are associated with and allow the survival of weeds: abundant seed, production; rapid population establishment; seed dormancy; long-term survival of buried seed; adaptation for spread; presence of vegetative reproductive structures; and ability to occupy sites disturbed by human activities (Dwight, 2009; Abdulraheem, 2018). There are approximately 250,000 species of plants worldwide; of those, about 3% or 8000 species behave as weeds (Dwight, 2009; Akobundu, 1998 and Akobundu *et al.,* 2016). Weeds are troublesome in many ways. Primarily, they reduce crop yield by competing for water, light, soil nutrients, and space. Other problems associated with weeds in agriculture include: reduced crop quality by contaminating the commodity; interference with harvest; serve as hosts for crop diseases or provide shelter for insects; limit the choice of crop rotation sequences and cultural practices; and production of chemical substances which are toxic to crop plants (allelopathy), animals, or humans (Dwight, 2009; Smith, 2016; Abdulraheem, 2018).

Cocoa (*Theobroma cacao* L.) is an important cash crop and major source of income to many smallholder farmers in the forest regions of West Africa. West Africa is currently leading in world cocoa production with about 70 %, while Asia and the Americas contribute about 16 % and 14 %, respectively. Cocoa is the most important cash crop that contributes to national economy in Nigeria. It is estimated that 90 % of worldwide cocoa production comes from smallholdings and most of this production occurs in areas of high biodiversity, of varieties and pest complexes-weeds inclusive.

MATERIALS AND METHODS

The main objectives of this trial was to predict weed growth characteristics in terms of densities, frequencies, importance value and diversities and, to use the predictions for selection of weed control measures that have some desired effects. Thus, a field experiment was conducted in June 2014 in two different agro-ecologies: The Cocoa Research Institute of Nigeria (CRIN), Ibadan (Lat. 7° 10' N, Long. 3° 52' E,) representing dry forest and CRIN, Owena (7^0 11' N, 5^0 01' E) Sub - station, Ondo State, Nigeria representing wet forest. The experiment was a split plot in a Randomized Complete Block Design (RCBD) with three replications per treatment. The varieties (CRIN Tc-1, CRIN Tc-2 and F3 Amazon obtained from the headquarters of CRIN, Idi-Ayunre in Ibadan) were allocated to the main plot and weeding regime (WR) into sub-plots as: WR1.UW1+WA4 (Unweeded in June +Weeded in July, August, September &October), WR2.UW2+WA3 (Unweeded in June &July +Weeded in August, September &October), WR3.UW3+WA2 (Unweeded in June, July &August +Weeded in September &October), WR4.UW4+WA1 (Unweeded in June, July, August &September +Weeded in October) with the two controls which did not vary, the plots were kept weed-free (treatment 5) and weed-infested (treatment 6) throughout. Plantain was used as a shade crop for the cocoa stands and was established a year before transplanting cocoa at a spacing of 3 x 3 m, (ditto for cocoa) and three stands of cocoa covering 3 x 6 m = (18 m^2) / treatment was used. Weeds were sampled once from one 50x50cm quadrate per sub-plot for each treatment. The data were analyzed by excel package of simple percentages;

Weed species diversity (H') was computed from weed density, according to Pielou (1969) as:

$H' = -\sum p_i \ln p_i$ ……………………………………………equation,

where p_i = density of each weed species (no.m^{-2}) and ln= natural logarithm.

Every month, data were taken from each plot for all the treatments. Only weed species with RIV ≥ 10 % will be discussed.

RESULT AND DISCUSSION

Table 1 gives appraisal of weed incidence across the three cocoa varieties (Tc1, Tc2 and F3 Amazon) during the trial in June, 2014. In Tc1 variety, a total of 54 weed types were collected and identified; 26 occurring in Ibadan, 28 at Owena and 12 at both locations. These 54 types cut across 42 species because some of the existing ones in Ibadan are found in Owena. Similarly, in Tc2 variety, 56 types were collected; 27 occurring in Ibadan, 29 at owena and 16 in both. The 56 weed types belong to 40 species. Consequently, in F3 Amazon variety, 62 weeds recorded; 28 were found in Ibadan, 34 at Owena and 16 in both locations; all belonging to 46 species.

Across locations and WR, individual weeds were less abundant in density (0-30 plants/m^2) in Tc1, Tc2 and F3. However, in **TC1** (Table 2)**,** *Chromolaena odorata* and *Desmodium scorpiurus* were distinctly widespread. These were followed by *Aneilema aequinoctiale* and *Oplismenus burmanii* which were appreciably widespread and the fairly widespread *Asystasia gangetica, Brachiaria deflexa, Momordica charantia* and *Sclerocarpus africanus.* Similarly, in **TC2** (Table 3)**,** *Chromolaena odorata* was distinctly widespread, compared to the widespread weeds like *Digitaria horizontalis, Ficus exasperata, Momordica charantia, Pouzolzia guineensis and Tridax procumbens.* In **F3** (Table 4), *Oplismenus burmannii* was distinctly widespread compared to the moderately widespread *Ageratum conyzoides, Digitaria horizontalis, Calapogonium mucunoides, Chromolaena odorata* and *Talinum traiangulare* and widespread *Aneilema aequinoctiale, Asystasia gangetica, Brachiaria deflexa* and *Sclerocarpus africanus.* All other weeds in (tables 2-4) recorded but not mentioned among the three varieties were not widespread. As per relative importance value (RIV) for the varieties, all the weed species were relatively low and similar in abundance (RIV ≤ 10 %) and are not to be discussed as they were not important.

Within locations and WR, generally weeds were neither abundant nor widespread in occurrence in the three varieties. Also within the location and WR but with respect to diversity (H'); in Tc1 variety (Table 2), weed diversity was distinctly high in WR1 (H' =2.33) at Owena, moderately high (H' =1.42 - 2.-04) in other treatments and lowest at WR5 (H' =0.63) in Owena. In Tc2 (Table 3), most diverse weed occurred in WR4 (H' =2.22) at Owena, moderately high (H' =1.07 - 2.08) in others and least in WR3 (H' =0.91) at Ibadan while in F3 (Table 4), the distinctly high weed diversity was in

WR5 (*H´* =2.18) at Ibadan and WR3 (*H´* =2.17) in Owena; moderately high (*H´* = 1.60 - 2.11) in other treatments and least diverse weed flora is in WR6 (*H´* =1.24) at Owena. Table 5 summarizes results on effects of weeding regime (WR) on weed species diversity (*H´*), Most diverse flora, occurrence and most occurred across three cocoa varieties in Ibadan and Owena (June, 2014).

The naming of the weeds (nomenclature) is of paramount importance in any weed identification studies as it helps in informing the farmer on the type of weeds existing in his plantation which can be a clue for their prevention and control (Idrisu *etal*., 2020). Akobundu (1998), Akobundu *et al* (2016) emphasized on proper nomenclature and provides best international guide and information on the taxonomy of weed species and how best they can be identified, classified and written. The diversity and complexity of weed flora in both experimental sites strongly confirm the documented reports of Ayeni *et al.* (1984), Smith (2017), Smith and Onamadi (2007), Smith and Alli (2005), Smith and Alli (2007) on the primary influence of tropical high rainfall and temperature on ecological weed growth and diversity.

The variations in weed species diversity across cocoa varieties, location and weeding regime strongly indicate the predominant influence of environmental factors, viz. soil productivity, crop competitiveness, varietal tolerance and climatic growth conditions of both crop varieties and weeds (Akobundu, 1987; Idrisu *et al*., 2021).

The higher weed flora diversity in WR1 across variety and location in June can be attributed to the prevalent early weed infestation at cocoa establishment; no weeding was done in the first month of cocoa establishment. The distinctly widespread occurrence of *C. odorata,* across varieties and locations during early cocoa establishment (June 2014) was due primarily to local distribution as widely documented in tropical agro-ecologies (Akobundu, 1987; Smith 2001) and weed growth habit (Akobundu *et al.*, 2016). The increase in weed occurrence across experimental sites resulted primarily from weed succession and adaptation patterns to the safe site conditions (Akobundu, 1987; Smith and Fasanmi, 2018; Idrisu *et al*., 2019) in establishing cocoa plantation, especially topsoil disturbance, soil moisture and temperature, impact of solar radiation on shallow weed seedbank, weed seedling emergence and survival of emerged weed seedlings.

Specifically, the overwhelming dominance of *C. odorata* during early cocoa seedling establishment (2014) was primarily due to its tenacity for vigorous regrowth from buds on cut stem-bases during manual weeding under cocoa canopy (Odukwe, 1964; Akobundu, 1987). *C. odorata* is a serious weed in oil palm, cocoa and rubber plants (Odukwe, 1964). The weed was reported to be the most problematic invasive species within protected rainforests (Struhsaker *et al*., 2005), where it prevents the regeneration of tree species in areas of shifting cultivation. Earlier studies specifically identified *C. odorata* as a common weed of cocoa plantations in Owena Local Government Area of Ondo State (Smith, 2000).] Judging from the widespread unappreciable weed RIV (≤10%) recorded across cocoa variety, location and weeding regime during this study, it is evident that none of the weed species encountered was a potential invasive weed problem.

CONCLUSION:

It therefore concluded that:

1. Identification studies help in informing on the type of weeds existing in plantation which can be a clue for their prevention and control.
2. Farmers should avoid early higher weed flora (weed infestation) at cocoa establishment by embarking on early weeding (WR1).
3. Farmers should check widespread occurrence of *C. odorata* by avoiding local distribution of it seeds and whole stem.
4. Farmers should prevent and control weed succession and adaptation patterns by making their safe site conditions unfavorable for them to grow and guide against increase in weed occurrence.
5. Dominance of *C. odorata* should be by preventing it regrowth from buds on cut stem-bases during manual weeding under cocoa canopy or establishment; instead, uproot them because of their problematic invasive nature.
6. Widespread unappreciable weed RIV (≤10%) recorded means none of the weed species encountered was a potential invasive weed problem thus, weeds in cocoa fields should not be allow to get to a threshold level before weeding them.

However, in spite of the inconsistent occurrence of most of the other weed species, *Aneilema aequinoctiale*, *Asystasia gangetica*, *Brachiaria deflexa*, *Digitaria horizontalis*, *Momordica charantia*, *Oplismenus burmanii* and *Sclerocarpus africanus* were apparently present as potential invasive weeds. There is therefore, a strong need to prevent their resurgence during seedling cocoa establishment across cocoa variety, location and weeding regime.

ABSTRACT

Field experiment was conducted during 2019 dry season at the Teaching and Research Farm of Faculty of Agriculture and Agricultural Technology, Abubakar Tafawa Balewa University, Bauchi, to determine the performance of two garlic varieties to different weed control methods. The treatments consist of two (2) garlic varieties: Ex- Sokoto and Ex-Kofa and four (4) weed control methods: Hoe weeding, Herbicides and Aqueous neem leaf extract and a control making a total of eight (8) treatment combinations. The treatments were laid out in a Randomized Complete Block Design replicated three (3) times. Data were collected on growth, yield, yield components and weed indices of weeds. The result of the experiments revealed significant (P≤0.05) variation among the two varieties tested on plant height, fresh bulb weight, cured bulb weight, fresh and cured yield per hectare and fresh weight of weeds. Ex- Sokoto produced taller plants and heavier bulb, higher yield (t/ha) and lighter fresh weed weight than Ex-Kofa. But there was no significant difference on number of leaves, cloves, and weed indices of weeds between the varieties except for fresh weed weight. Where plots with Ex- Kofa gave higher fresh weed weight (263.67g/m^2) and the lowest was obtained from Ex- Sokoto (196.83/m^2). Further, results of the experiment showed significant (P≤0.05) difference among the weed control methods, where hoe weeded treatments, herbicides and neem extract gave better values for almost all the character measured while control plots produced the lowest. Based on the result of this findings therefore, Ex- Sokoto variety of garlic and either hoe weeding, herbicides and or aqueous neem leaf extract may be adopted by farmers for better productivity of garlic in the study area

Key words: Garlic, Varieties, weed control methods, Weed indices

INTRODUCTION

Garlic (*Allium sativum* L.) is an annual vegetable crop of the family alliaceae and genus allium. It is widely recognized as a valuable spice for seasoning and flavouring food and a popular remedy to various ailments and physiological disorder Leech, (2018). Different varieties of garlic exist, which differ in colour, bulb size, clove number and even Sulphur content and bulb yield Usman *etal*., (2016). Yield variations were recorded in different garlic varieties which occur as a result of differences in genetic make-up of the plants environmental factors, agronomic practices among others Weeds constitutes a major problem in garlic production as it competes for both above ground and below ground resources of production which includes: sunlight, water, nutrients etc. weed control remain a major challenge to garlic farmers as it is closely spaced in the field. Hoe weeding is tedious and labour intensive while the use of synthetic herbicide is expensive and indiscriminate use of it is hazardous to human health and environments (Naeem *etal*., 2018 and Ihsan *et al*., 2015). Due to increasing emphasis in organic farming and environmental protection, attention has been shifted towards allelophaty, which is a biological phenomenon by which one organism produces biochemical that influences the growth survival, development and reproduction of another. Allopathy is use in weed control and a promising way to utilize it in weed control is by the use of water extracts of allelopathic plants as herbicides (Dhima *et al*., 2009; Singh *et al*., 2005; White *et al*., 1989). So many researchers have reported the application of allelopathic plant water extracts for weed suppression (Dhima *et al*.,2009; Jamil *et al*., 2009). Plants known to have allellophatic effects includes *Azadirachta indica*, *Eucalyptus spp,* Sorghum (stem, leaves, and root) garlic. etc. (Weston *et al*., 2013; Won *et al*., 2013). Based on this therefore, this experiment was conducted to determine the performance of two garlic varieties as influenced by different weed control methods.

MATERIALS AND METHODS

Field experiment was conducted during 2019 dry season at the Teaching and Research Farm of Faculty of Agriculture and Agricultural Technology,

ISSN: 2814-0508

ATBU, Gubi Campus Bauchi (10°22′ N, 9°47′E) and 609.3m above sea level, to determine the performance of two garlic varieties under different weed control methods. The treatments consist of two varieties of garlic (Ex-Sokoto, and Ex-Kofa), four weed control methods (herbicides, hoe weeding, aqueous neem leaf extract and a control) making a total of eight treatment combination and these were replicated three (3) times. Garlic bulb selected for planting were separated into their individual cloves and soaked overnight a day to planting as this practice was reported to enhance germination in garlic. Planting was done at a spacing of 20x10cm inter and intra row spacing.

Preparation of the Aqueous Neem Leaf Extract

The neem leaves were obtained from Bauchi State College of agriculture. The leaves were air dried and grounded into powder, the powdered plant material were diluted with water at 1kg to 20liter of water at rate of 40kg/ha (Anwari *et al*. 2003). The extract was applied pre-emergence and at six (6) weeks after emergence**.** Data were collected on plant height, number of leaves, fresh bulb weight, cured bulb weight, number of cloves, fresh yield, cured yield in ton/ha. Weed parameters measured were: number of weeds/m2, fresh and dry weed biomass, weed control efficiency, weed index and the level of weed infestation. All data collected were subjected to analysis of variance (ANOVA) and Duncan multiple range test was adopted in separating the significantly different means.

RESULTS AND DISCUSSION

Plant Height and Number of Leaves of Garlic

The plant height and number of leaves of garlic differed significantly ($p \leq 0.05$) between the two varieties at both weeks after planting, where Ex sokoto gave taller plants than Ex Kofa. However, number of leaves of garlic did not show any significant variation among the varieties (Table 1). This could be due to genetic make-up of the plant and hence they differ in their ability for exploiting environmental factors such as light carbon dioxide water atmospheric humidity nutrients etc. This result is in conformity with the findings of (Rahman *etal*., 2020: Usman *etal*., 2016) who reported variations between garlic varieties in terms of growth parameters. The effect of weed control methods on plant height and number of leaves of garlic was significant ($p \leq 0.05$). where hoe weeding, herbicides application and application of aqueous neem leaf extract produces taller plant while the shorter plant was produced by the control application. This indicates that both hoe weeding, herbicides and neem leaf extract application have no negative effect on plant growth and to same extents have same capability of managing weeds since they produced statistically the same value for the plant height (Table 1). This finding is in agreements with the work of (Cheema *et al.,* 2004) who reported aqueous extracts of sorghum as plant growth promoters and increased yield of wheat by up to 21%

Yield and Yield Components of Garlic

The results obtained on yield and yield components of garlic revealed significant ($p \leq 0.05$) variation on almost all the characters measured except for number of cloves of garlic (Table 2)

Number of Cloves of Garlic

There was no significant difference between the varieties for number of cloves of garlic, however weed control methods significantly influenced number of cloves of garlic, where hoe weeded treatments produced more cloves which is statistically similar with the herbicides and neem leaf extract application, while fewer cloves was from the control application (Table 2). This shows that aqueous neem leaf extract did not suppress the growth of garlic and also formation of bulb and cloves of garlic

Fresh and Cured Bulb Weight of garlic

There was significant difference for both fresh and cured bulb weight of garlic between the varieties, Ex-Soko gave heavier fresh and cured bulb than Ex-Kofa. This could be attribute to the difference in genetic make-up of the varieties, Ex-Sokoto might be having high tendency of utilizing the resources of production and ability to convert it into dry matter. This finding is in agreement with that of Gashaw *et al*. (2020) who reported variation in growth and yield characters of garlic among different varieties of garlic including number of cloves. Further, weed control methods have significantly ($P \leq 0.05$) influenced both fresh and cured yield of garlic. Hoe weeding gave heavier fresh and cured bulb weight of garlic of up to 33g and 19g respectively while the lighter fresh and cured bulb weight (16g) and (9g) respectively was from the control treatment. (Table 2).

Fresh and Cured Yield of Garlic

Both fresh and cured bulb yield of garlic showed significant ($P \leq 0.05$) variation between the varieties tested, Ex- Sokoto gave higher yield than Ex- Kofa. With regards to weed control methods, hoe weeded treatments produced higher fresh and cured yield of garlic while herbicides and neem leaf extract application produced statistically the same

ISSN: 2814-0508

yield and lowest yield was from the control treatment. This is supported by the findings of (Kowthar *et al*., 2019) who reported increase in yield of quinoa by the application of aqueous extract of garlic and eucalyptus (Table 2)

Weed control efficiency

There was no any significant difference observed between varieties of garlic tested on weed control efficiency, however, significant difference was recorded between the different weed control methods. Where hoe weeding gave the highest weed control efficiency of (90%), herbicide recorded 59%, neem extract achieved 50% weed control efficiency (Table 3).

Table 3: Effect of variety and weed control methods on Weed Indices of garlic

V × WCM = Variety x Weed control methods, NOW= Number of weeds, FWB= Fresh weight of weeds, DWW= Dry weight of weeds, WCE= Weed control efficiency, WI= Weed index, WIF= Weed infestation

Means followed by the different letter(s) within a treatment group are significantly different using Duncan Multiple Range Test (DMRT

Weed index

The two varieties of garlic tested showed no significant difference on weed index. But significant variation was observed between the weed control methods on weed index, where herbicides application gave lower weed index (25%) and the higher weed index (68%) was from control treatment. However, application of neem extract gave weed index (37%) (Table 3). Weed index is reduction in yield due to effect of weeds.

Weed Infestation

There was no significant difference ($p \leq 0.05$) with regards to weed infestation between the two varieties, however, significant variation was observed between the weed control methods on weed infestation, where higher weed infestation (60%) occurred with control treatments while lower weed infestation were recorded with hoe weeding (12%) and was statistically the same with herbicides and aqueous neem leaf extract (15%) methods of weed control (Table 3). This indicated the potential of neem leaf extract in reducing the level of weed infestation in garlic is similar to that of herbicides. This has support of the work of (Mishra, 2014; who reported allelophatic effect of neem leaf extract on seed germination and growth of some agricultural crops, (Lawal *et al*., 2011) who revealed suppression of both germination and growth of cowpea as a result of application of neem leaf extract and that of (Xuan, 2004), who reported that neem tree strongly inhibits germination and growth of several species of plants: *Daucus carota, Raphanus sativus, Oryza sativa etc*

Conclusion and Recommendation

Based on the result of this finding, weed control methods had influenced both growth, yield, and weed indices of garlic varieties. Hoe weeding gave better values for the growth and yield of garlic. For weed control methods however, herbicides and aqueous neem leaf extract showed similar potentials in reducing the effect of weed in garlic. Therefore, further research is recommended on the rate, timing of application and selectivity of neem leaf extract in managing weeds as it performed the same with herbicides in managing weeds, hence it showed a great potential as natural herbicides.

Abstract

Field experiments were carried out at the Federal College of Agriculture, Moor Plantation, Ibadan, Nigeria in 2016 and 2018 to evaluate the effects of different methods of weed control on the growth and yield components of tomato. The treatments consisted herbicide (Pendimetalin), manual weeding using hoe, mulching with grass plant residues, cover crops (life mulching), plastic mulching, while the control was left weedy. Randomized complete block design (RCBD) was used for this experiment with three replicates. Data collected were analyzed using analysis of variance, and significant means were separated by Duncan's multiple range test (DMRT) at 5 % probability. Grass mulching had the highest tomato yield (i.e. No of fruits/plant and weight of fruits/plant) in both years. Yield in grass mulching was significantly higher than other treatments as yield decreased in the order of grass mulching > herbicide > plastic mulching > hoe weeding > use of cover crops > control (weedy check) treatment. In weed control, cover crop had higher weed biomass (45.70 and 40.47g m^{-2}), respectively apart from weedy check which had the highest weed biomass of 90.25, 80.45 g m^{-2}, while plastic mulch had the least weed biomass of 4.45 and 9.15 g m^{-2}.

Key words: Tomato, weed control, mulch, herbicide, hoe weeding

INTRODUCTION

Tomato (*Lycopersicum esculentum* Mill) belongs to the family Solanaceae. It is a popular and nutritive crop ranking next to potatoes in world's vegetable production. It is an important source of minerals and antioxidant such as carotenoids, lycopene, vitamins C, E and phenolic compounds which have a key role in human nutrition in prevention of certain cancer and cadiovascular diseases (Adalid *et al*., 2004).

Tomatoes are consumed in a number of ways, including sun-dreid tomatoes, tomato sauce, tomato juice, tomato soup, tomato ketchup and fresh as salad (Frusciente *et al*., 2007). It is an important cash-generating crop for small scale farmers, and it also provides employment in its production and processing industries (Jiregna *et al*., 2011). Despite this importance, in Nigeria, the average yield is low. The performance of tomatoes under high rainfall and humid conditions of southern Nigeria is poor compared to northern dry savanna environment (NIHORT, 2000).

In many agricultural systems around the world, competition from weed is also one of the major factors reducing crop yield and farmers' income (Knott, 1992). Of all the constraints limiting tomato production, weed seems to have the most deleterious effect causing yield reduction (Sanok *et al*., 1979; Usoroh, 1983, Sinha and Lagoke, 1984). Weeds reduce yield by competing for space, light, water and nutrients thereby weakening crop stands and reducing harvest efficiency (Abbassi *et al*., 2013).

Some weeds can also increase other pest problems by serving as alternative hosts for insects, diseases or nematodes. Weeds appear to have the most deleterious effect causing yield reduction of between 53 and 67 % in Maryland (Sanok *et al*., 1979; Usoroh, 1983; Sinha and Lagoke, 1984), 40 – 82 % in Nigeria (Adigun *et al*., 1993), 70 % in Pakistan (Bakht and Khan, 2014). Adigun (2000) reported that unrestricted weed growth throughout the crop life cycle resulted in 92 – 95 % reduction in tomato fruit yield. The weed control methods practiced in tomato production include cultural, mechanical, chemical and integrated weed management (Ashton and Monaco, 1991).

Since weed seems to have the most deleterious effect causing yield reduction, it is necessary to evaluate different methods of weed control in order to choose the best method; hence, the objective of the project is to determine the effects of different methods of weed control on the growth, yield components and yield of tomato.

MATERIALS AND METHODS

Field experiments were carried out in 2016 and 2018 at the Federal College of Agriculture, Ibadan, southwest of Nigeria (Lat. $7^0$22`30`` N and Long. $3^0$50130``E. Ibadan is characterized by bimodal rainfall distribution pattern with long raining season from March to July, a break in August and a short spell between September and early November.

Soil samples were collected from different points on the farm with Auger at a depth of 0 – 30 cm, air-dried, ground, and bulked for laboratory analyses. The site was cleared manually, ploughed and harrowed twice. The experimental site was marked out with garden line and meter rule. Pegs were used to demarcate the plots and leveled beds were prepared.

The experimental design was randomized complete block design (RCBD), replicated three times. There were six treatments in each replicate. The plot size was 3 x 3 m with alleyway of 0.5 m among the plots and replicates. Total land area used was 236.5 m^2. Treatments used were herbicides (Pedimetalin), hoe weeding, grass mulch, plastic mulch, and control (weedy plot).

The plastic mulch was laid before transplanting of seedlings, which was done through the openings made on it at 50 x 50 cm. herbicide (Pedimetalin) was applied before transplanting. The dried grass was also applied before transplanting leaving a little space for two plants. Hoe weeding was carried out at 3 and 8 weeks after transplanting (WAT). Life mulch was planted 3 WAT, while the control was left un-weeded from time of planting to the end of the experiment.

Tomato R10 Grande cultivar was obtained from certified Seed Store. It was planted in the nursery 6 x 4 m bed size and uniform and vigorous seedlings were transplanted to the experimental field at 5 Weeks after planting (WAP). 4 plants were selected randomly at the center and tagged for data collection.

Data were collected on plant height, leaf length and breath, stem girth, number of branches, number of fruits per plant, fruit length and fruit diameter, number of days to 1st flowering, number of days to 50 % flowering and yield per plot. These were subjected to analysis of variance (ANOVA), while means were separated using Duncan Multiple Range Test (DMRT) at 5 % level of probability.

RESULTS AND DISCUSSION

The soils were slightly acidic in 2016 and 2018 with pH of 5.71 and 6.80, the organic matter and total nitrogen were low (4.85, 6.59g kg and 0.09, 0.38%) respectively, available phosphorus were moderately low with 7.71 and 5.11mg kg, while the exchangeable cation were low. The textural class of the soils sandy (Table 1).

Table 1. Physical and chemical properties of pre-cropping soil

Parameter	2016	2018
pH	5.71	6.80
Available phosphorus (mg kg^{-1})	7.71	5.11

Plant height.

In 2016, mulching with grass had the highest plant height (69.90cm) but not significantly different from 67.77 and 64.30 cm in use of herbicide and hoe, respectively. but this was significantly different from the use of cover crops (58.40 cm), which was not different significantly different from plastic mulching (56.90cm). However, the least (45.73cm) plant height was in weedy

ISSN: 2814-0508

cheek (control) treatment. In 2018, the use of herbicide had the highest (70.20 cm) plant height which was not different significantly from cover crop (65.50cm), plastic mulching (64.92cm), grass mulching (64.40cm), hoe weeding (60.70cm), but significantly different from (54.20cm) in the control treatment which was least in plant height. These results support the findings of Deoteau et al. (1998) who reported mulching as a means of controlling weed, significantly affected the growth of tomato compared to no mulching and the grass mulching conserved sufficient moisture that enhanced the growth of tomato producing tallest plant height and maximum leaf area index (Table 2).

Table 2.: Effect of different methods of weed control on growth parameters of tomato

Treatment	Plant height (cm)		Leaf area index (cm)		No. of branches		Stem girth (cm)	
	2016	2018	2016	2018	2016	2018	2016	2018
Herbicide (Pendimetalin)	67.77a	70.20a	18.40ab	30.30ab	0.33b	5.88a	1.27ab	1.30a

Leaf area index (LAI)

The treatment had no significant on LAI of tomato in 2016. From the results, grass mulching had the highest (20.22cm) LAI > hoe weeding (18.84cm) > plastic mulching (18.54cm) > herbicide(18.40cm) > cover crop(17.86cm) > weedy check (15.39cm). In 2018, the treatment had significant effect on LAI of tomato where hoe weeding (37.00cm) was the highest, which was not different significantly from grass mulching (36.60cm) plastic mulching (33.60cm) and herbicide (30.30cm) but different significantly from weedy check and cover crop (25.96 and 25.60 cm) respectively. Plastic mulching, herbicide, weedy check and cover crop are not different significantly from one another with 33.60 > 30.30 > 25.90 > 25.60 cm, respectively.

Number of branches

Different methods of weed control had significant effects on the no. of branches where grass mulching had the highest (2.50) no. of branches which was not different significantly from hoe weeding (2.00) > cover crop > (1.60) plastic mulching (1.25), but the four treatments were different significantly from weedy check (0.42) and herbicide (0.33) in 2016.

In 2018, herbicide had the highest (5.87) no. of branches which was different significantly from plastic mulching, grass mulching, cover crop, hoe weeding and control (weedy check) having values of 4.30, 2.60, 2.43, 2.27 and 2.22, respectively, also plastic mulching 4.30 was different significantly from grass mulching, cover crop, hoe weeding and control values 2.60, 2.43, 2.27, and 2.22 respectively.

Stem girth

The treatments had significant effects on the stem girth of tomato where grass mulching had the highest (1.63cm), which was not different significantly from hoe weeding (1.61 cm), cover crop (1.40 cm), plastic mulching (1.34 cm) and herbicide (1.27 cm), but different significantly from weedy check (0.84 cm) in 2016.

In 2018, the treatments had significant effects on stem girth where grass mulching had the highest (1.33 cm), which was not different significantly from herbicide and plastic mulching with 1.30 cm, but significantly different from hoe weeding, cover crop and the control with values of 1.07 > 1.00 > 0.99 cm, respectively.

Effect of different methods of weed control of reproductive character of tomato

The treatments had significant effects on the no. of days to 1st flower production (Table 3). In 2016 and 2018, the control had the highest (80.15, 83.23 days) to produce the 1st flower which was not significantly different from all other treatments, but different significantly from herbicide which brought out its 1st flower first. The treatments had no significant effects on no. of days to 50 % flower production in 2016 and 2018.

Table 3. Effect of different methods of weed control on reproductive character of tomato

Treatment	No. of days to 1st flowering		No. of days to 50 % flowering	
	2016	2018	2016	2018

Effect of different methods of weed control on yield and yield components of tomato

Effects of different methods of weed control on yield components are presented in Table 4. The treatments had significant effects on the fruit length in 2016 and 2018. Herbicide treatment had the highest (5.11 cm in 2016 and 5.20 cm) in 2018, which were not different significantly from cover crop (5.01, 5.10 cm), hoe weeding (4.79, 4.80 cm), plastic mulching (4.75, 4.93cm) but different significantly from grass mulching (3.30, 3.40cm) and weedy check (3.41, 3.57cm). Also, the treatments had significant effects on fruit diameter in both 2016 and 2018. Cover crop had the highest (4.57 and 4.23 cm) in 2016 and 2018 respectively which was not different significantly from herbicide (4.32, 4.23cm), plastic mulching (4.20, 4.06cm) and hoe weeding (3.65, 3.73cm), but different significantly from grass mulching (2.80, 2.73cm) and the control (2.51, 2.73cm).

The treatments also had significant effects on the no. of fruits per plant in the years 2016 and 2018 where grass mulching had the highest (4.58, 4.24) no. of fruits per plant. This was not significantly different from hoe weeding (3.42, 3.12), plastic mulching (3.35, 3.30), cover crop (3.33, 3.03), but different significantly from herbicide (2.33, 2.25) and the control (2.42, 2.32), but hoe weeding, plastic mulching, cover crop, the control and herbicide are not different significantly from one another.

Different methods of weed control had significant effects on fruit weight per plant in 2016 and 2018 (Table 4) where grass mulching had the highest (180.95, 175.35 g) fruit weight per plant which was > plastic mulching (128.20, 120.50 g) > hoe weeding (102.91, 100.55 g) > cover crop (121.50, 115.57 g) > control (74.05, 72.97) herbicide and weedy control are not different significantly from one another. Different methods of weed control had significant effects on tomato yield in 2016 and 2018 (Table 4) where grass mulching had the highest yield of 2.86, 2.63 t ha^{-1}. The yield was significantly higher than herbicide (2.41, 2.36 t ha^{-1}) > plastic mulching (2.00, 2.05 t ha^{-1}) > hoe weeding ≈ cover crop (1.91, 1.85 t ha^{-1}) > control (1.39, 1.33 t ha^{-1}). The results conformed with the finding of Kumer *et al*. (1995) who observed that mulching significantly increased the number of fruits per plant compared to weedy check (control).

Effect of different methods of weed control on weed biomass

In Table 5, the highest (98.25, 80.45 g) weed biomass occurred in the control (weedy check) which was significantly higher than all other treatments where plastic mulching had the lowest (4.45, 9.15 g) weed biomass. The order of weed control from the lowest was plastic mulching< grass mulching < herbicide < hoe weeding < cover crop < control (weedy check). This result is in line with the finding of Sanders (2001) who reported that black plastic mulching provides good weed control.

CONCLUSION

It could be concluded from this study that grass mulching has the potentiality to increase the yield of tomato. Farmers in Ibadan may use grass mulching

ISSN: 2814-0508

in order to increase total yield per unit area of land in tomato production which will result into low weed infestation, weed biomass and effectively control weed of tomato up to harvest.

ABSTRACT

The experiment was conducted at the Teaching and Research Farm of Kabba College of Agriculture, Division of Agricultural Colleges, Ahmadu Bello University, Kabba campus to study the effect of weed control methods on weed persistence, growth and yield of Egusi melon in southern Guinea Savannah agro ecology of Nigeria. The trial consisted of six treatments laid out in an experimental plot size of 3 m x 3 m each in a randomized complete block design (RCBD), with three replications. The treatments were (WC= plot weedy control, WF=weed free plot, HW4 and 8=hoe weeding at 4 and 8 weeks after sowing (WAS), ATP+HP8= atrazine at 2.5 a i at planting plus hand picking at 8 weeks after sowing, GMAP+HP8= grass mulch at planting plus hand picking at 8 WAS and F= SH3WBS+AP+HP8= application of systemic herbicide (Round up) at 4 l/ha 3 week before sowing (WBS) plus atrazine a day after sowing plus hand picking at 8 WAS). All plots with weed control were better than the weedy plots (control) in growth and yield. The highest yield was recorded in plots with systemic herbicide 3 WBS and atrazine at planting. Plot with grass mulch at sowing plus handpicking at 8 weeks after sowing produced yield higher than plot with weed free and plot with atrazine at planting plus hand picking at 8 WAS. All the weed control plots produced similar weed density, weed fresh weight, weediness of the field and melon canopy cover. The least melon canopy cover occurred in the plots without weed control methods. All the weed control plots produced similar weed control effects compared with weedy plots. For optimum yield of melon, farmers could use round up 3 weeks before sowing + atrazine at planting + hand picking at 8 WAS to enhance melon season-long weed suppression and guarantee profitable melon productivity.

Key words: Egusi melon, weed control, growth, yield, productivity

INTRODUCTION

Melon (*Colocynthis citrullus* L.*)*, popularly known as Egusi-melon is an important crop in African, especially Nigeria. It can tolerate low rainfall. It is cultivated within the savannah and forest vegetation belts (Ekpo *et al.,* 2010). In Nigeria, it is cultivated as sole crop but it could be intercropped with other annual crops. it is cultivated for its seeds which are prepared into condiments used in preparing soup and various dishes (Olaniyi, 2008; NAERLS-PCU, 2005). Melon performs best in a fertile, well drained, loamy soil, medium to near neutral pH, gentle but regular rainfall, interspaced with plenty of sun shine for increase in yield (Olaniyi, 2008). In southern Nigeria, Egusi melon is usually grown mixed with other crops such as cassava and maize by most famers who practice mixed cropping (Ekpo *et al*., 2010). Egusi melon is abundant in Nigeria, where it is cultivated in over an area of 361,000 ha, with yield of about 347,000 tonne per annum (Udensi and Oyeye, 2016). Melon is a short duration or short season crop, it provides food, and most importantly generates income to the farmers early in the season.

The major problem limiting productivity and increased land use for melon cropping system in the southern part of Nigeria is weed. Different weed control methods are used in crop production. Manual weeding is an effective means of controlling weeds (Fischer and Hill, 2004). The predominant method of weed control used by smallholder farmers in Nigeria is hoe weeding (Chikoye *et al*., 2002). Darkwa *et al*. (2001) and Chikoye *et al*. (2002) reported that 25 – 40 people are needed to weed one hectare of maize farm and this may account for 50 – 80 % of total labour budget. The mass migration from rural farm areas to urban centre increases cost of labour (Fischer *et al*., 2004) and also encouraged dependence on herbicides usage (Fischer *et al*., 2004). Delayed weeding causes significant crop losses (Chikoye *et al*., 2004) especially when economic threshold of weed infestation is exceeded. Hoe weeding is uncongenial and laborious (Aluko *et al.,* 2017). However, resource poor farmers have depended on this manual weeding method for a long time. Like many other crops grown in the tropics, melon is susceptible to early weed competition during the

ISSN: 2814-0508

first 3 to 4 weeks after planting. Weed competition reduces canopy development and predisposes the crop to pest and disease infestation. Absence of weed control in crop farm resulted to crop losses of up to 100% (Nyam, 2005). For full expression of its genetic potentials and improvement in yield capacities, one of the operations in crops production is weed management (Madukwe, 2000). Hand weeding is probably the oldest method of weed control and consists of hand-pulling, hand-slashing and hoeing which have consistently proved inefficient and costly too. In technologically advanced countries, hand pulling is used merely to supplement other improved weed control methods (Kerkhoven, 2003). The use of herbicides for weed control have not only been found effective, but have been proven to be cheap if applied timely and correctly (Chikoye *et al.,* 2001). Similarly, Chikoye *et al.* (2002) have shown that chemical control was cheaper than hoe weeding.

Among pre-emergence herbicides, atrazine and metolachlor at 2.5 kg a.i./ha, fluometuron at 2.0 to 3.0 kg a.i./ha or diuron at 2.0 kg a.i./ha used singly or in combination with alachlor or metolachlorat 3.0 and 2.0 a.i./ha respectively have proved effective for weed control in the humid tropics (Akobundu, 1980). All of these herbicides were also listed as the common herbicides for weed control in the middle belt of Nigeria. The objective of the study was to assess the effect of weed control methods on weed persistence, growth and yield of Egusi melon in Southern Guinea Savannah agro ecology of Nigeria.

MATERIALS AND METHODS

The experiment was conducted at the Teaching and Research farm of Kabba College of Agriculture, Division of Agricultural Colleges, Ahmadu Bello University, Kabba (Lat. 7.8231^0 N and Long. 6.0732^0 E) in Southern Guinea Savannah agro ecology of Kogi State, Nigeria. The area is characterized by a bimodal rainfall pattern which starts in late March and ends in late July while the short rainy season extends from September to late October after a dry spell in August. The soil order is an Ultisol (Moss, 1957). The site was left fallow for three years after it was cropped to maize and cassava for two years prior to the establishment of the experiment.

Land preparation

The experimental site was slashed and tilled manually using cutlass and hoe, respectively, the land was leveled using a shovel. Soil samples were collected at a depth of 15 cm diagonally across the plot and bulked, and after thorough mixing a sub sample was taken to the laboratory for chemical analysis. The soil of the study site belongs to the Ultisol class with silt 18.1 %, clay 21.6%, sand 60.3% (Sandy clay loam) pH 6.3, TOC 1.57%, TON 0.19 %, 3.41 mg/kg P, 0.26 cmol/kg K, 2.47 cmol/kg Mg and 2.66 cmol/kg Ca (Table 1).

Treatments plan and application

The trial consisted of six treatments laid out in an experimental plot size of 3 m x 3 m each in a Randomized complete block design (RCBD), with three replications. The treatments are WC= plot weedy control, WF=weed free plot, HW4&8=hoe weeding at 4 and 8 weeks after sowing, ATP+HP8= atrazine at 2.5 a i at planting plus hand picking at 8 weeks after sowing (WAS), GMAP+HP8= grass mulch at planting plus hand picking at 8 WAS and F= SH3WBS+AP+HP8= application of systemic herbicide (Round up) at 4 l/ha 3 week before sowing (WBS) plus atrazine a day after sowing plus hand picking at 8 WAS. Planting was done on 1st of April, 2015 at a spacing of 75 cm x 75 cm. Two seeds were sown per hole which was later thinned down to one plant per stand three weeks after planting giving a plant population of 17,778 plants per hectare. The three inner rows were considered the net plot and five plants from the net plot were tagged from which the growth and yield parameters were recorded.

The crops were sprayed with lamdacyahalothrin as Karate (insecticide) and benomyl (benlate) fungicide at the rates of 2 litres and 1.5kg/ha respectively at 6 WAS to protect the plants against insect pests and fungal diseases (Eifediyi and Remison, 2009). Harvesting of the Egusi melon fruits commenced at twelve weeks after planting when the fruits had turned deep green in colour. Harvesting was done by handpicking the mature fruits.

The parameters recorded were vine length, number of leaves per plant, leaf area, yield and yield components. Egusi melon vine length was measured by using a flexible tape rule. Number of leaves was assessed by visual count of the leaves and the leaf area was assessed by the dry weight method. At harvest, the number of fruit per plant was counted and recorded, weight of individual fruit was taken with the use of measuring scale and recorded. The fruits were broken and left for 7 days after which the seeds were extracted and number counted and recorded and weight of seed yield per was recorded. Field evaluation of weed characters

ISSN: 2814-0508

of the field was conducted by panels of judges consisting of five (5) men, four (4) women and a youth (staff and student). The plots were presented in succession and panel members were allowed to judge the level of weed infestation.

Statistical analysis

Data collected were subject to the analysis of the variance (ANOVA) and treatment means were separated using Duncan Multiple Range Test when the difference between the averages was significant with the threshold of 5%.

RESULTS AND DISCUSSION

The results of the pre-planting soil analysis are presented in Table 1. The soil was sandy, clay, loam and relatively low in nitrogen, phosphorus and exchangeable potassium but slightly acidic. The organic matter level and total porosity were 1.57% and 38.8% respectively. The soil has the fertility potential to support the growth of Egusi melon.

Effect of weed control methods on the growth and yield parameters of Egusi melon are presented in Table 2. Significant differences were observed in all the growth and yield characters evaluated. Vine length of Egusi melon ranged between 283.6 and 103.2 cm. The longest vine length occurred in plots with atrazine at planting plus hand picking at 8 weeks after sowing, this was followed by plots with application of glyphosate (systemic herbicide) before planting plus application of atrazine a day after planting plus handpicking at 8 weeks after sowing (WAS). Plots with weed free then followed. Plots with hoe weeding at 4 and 8 WAS recorded the least value among the treated plots. However, weedy plots (control) recorded the shortest vine length of 103.2cm (Table 2).

Legend: WC= plot weedy control, WF=weed free plot, HW4&8=hoe weeding at 4 and 8 weeks after sowing, ATP+HP8= atrazine at2.5 a i at planting plus hand picking at 8 weeks after sowing (WAS), GMAP+HP8= grass mulch at planting plus hand picking at 8 WAS and F= SH3WBS+AP+HP8 application of systemic herbicide (Round up) 3 week before sowing (WBS) plus atrazine a day after sowing plus hand picking at 8 WAS.

Numbers of leaves per plant was significantly affected by different weed control method used. Number of leaves produced was highest in plot treated with atrazine at planting plus handpicking of weeds at 8 WAS (241.3 leaves). This was similar to plots treated with hoe weeding at 4 WAS plus handpicking at 8 WAS. Plots with systemic herbicide (Round up) 3 weeks before sowing (WBS) + Atrazine at planting, weed free plots and plots with grass mulch at planting + hand picking at 8 WAS produced similar effects. Plots with no weed control produced the least leaves and the value was significantly inferior to plots with weed control methods.

Leaf area was significantly different due to the weed control method used. Leaf area in melon ranged between 43.8 to 116.7m^2. Plots with atrazine application at planting + handpicking at 8 WAS recorded highest leaf area, this was followed by plots with systemic herbicide at 3 WBS plus hand picking 8 WAS. Plots hoe at 4 WAS also followed. Grass mulch plot recorded leaf area of 109.4m^2 while the least leaf area among the treated plots was recorded in weed free plots. The leaf areas of all the treated plots were significantly better than weedy plots.

The effect of weed control methods on yield parameters of Egusi melon are presented in Table 2. Number of fruits per plant and weight of individual fruit ranged between 2.42 to 7.48 and 0.36 to 1.26 respectively. Plots with weed free, hoe weeding at 4 WAS plus handpicking at 8 WAS, atrazine at planting plus handpicking at 8 WAS and plots with systemic herbicide 3 weeks before sowing + atrazine at planting gave similar number of fruits per plant and individual fruit weight. All these were significantly superior to weedy plots.

Significant differences were observed in the number of seeds per fruit due to the different weed control methods used. Plots with weed free plants recorded the highest number of seeds per fruit but heaviest seeds occurred in plots with systemic herbicide 3 weeks before planting plus atrazine at planting which produced similar numbers of seeds per fruit with weed free plots. Plots with hoe weeding at 4 WAS plus handpicking at 8 WAS and plots with atrazine at planting plus hand pick plots. The highest seeds among the treated plots occurred in plots with grass mulch at planting plus handpicking at 8 WAS. The seed yields of all the treated plots were better than the weedy plots (control).

The highest seed yield per ha was recorded in plots treated with systemic herbicide 3WBP plus atrazine at planting (4.93 t ha^{-1}), this was significantly superior to plots with weed free, hoeing at 4WAS plus handpick at 8WAS and grass mulch at planting plus handpick at 8 WAS that produced similar seed yield per ha. Weedy plots recorded the least seed yield per ha (1.34 t ha^{-1}).

All plots with weed control were better than the weedy plots (control) in growth and yield. This suggested that weed competition in weedy control plots were critical. This is in line with the report of Aluko *et al.* (2017); Ajibola and Modupeola (2014) who reported that weedy control plots suffer critical reduction in growth and yield. Plot with hoe weeding every week (weed free plot) produced lower yield compared to other weed control methods used. The lower yield recorded could be due to constant interfering with the root set up of the crop. Also, flowering distortion during hoeing could lead to premature falls of the flowers which resulted in lower yield of the crop.

The highest yield was recorded in plots with systemic herbicide 3 WBS and atrazine at planting. Chemical weed control has been reported to be effective (Adigun *et al*., 1993; Nazeer *et al.,* 2004 and Korieocha *et al.,* 2011). The combination of this chemical reduced early weed competition, prolonged season weed suppression and improved melon yield.

Plot with grass mulch at sowing plus handpicking at 8 weeks after sowing produced yield higher than plot with weed free and plot with atrazine at planting plus hand picking at 8 WAS. Aluko *et al.,* 2017 opined that mulching plus handpicking reduces weed flushes as a result of mulch barrier, environmental sieve was imposed that prevented weed seeds germination. James (1999) reported that vegetation germinant is eliminated by mulch material used and re-established following the deterioration of mulch materials, this could be responsible for higher yield in mulch plots.

The effect of weed control methods on weed density, wood fresh weight, weediness of the field and melon canopy are presented in Table 3. Significant differences were observed in weed density, weed fresh weight, weediness of the plot were fresh weight and weediness of the plots were highest in plot without weed control. All the weed control plots produced similar weed density, weed fresh weight, weediness of the field and melon canopy cover. The least melon canopy cover occurred in the plots without weed control methods.

Table 3. Effect of weed control methods on weed characters

Treatments	Weed density	Weed fresh weight (g/m2)	Weediness of the fluid (0 -5)	Melon canopy cover (0 – 5)
WC	127a	296.41a	9.63a	3.16b
Weeding Weekly (WF)	02b	4.86d	0.04b	8.41a
HW4&8	21b	42.68bc	1.14b	8.06a
ATP+HP8	18b	34.84c	1.28b	7.89a
GMAP+HP8	27b	45.38bc	2.04b	8.34a
SH3WBS+AP+HP8	26b	53.49b	2.16b	8.27a

Legend: WC= plot weedy control, WF=weed free plot, HW4&8=hoe weeding at 4 and 8 weeks after sowing, ATP+HP8= atrazine at2.5 a I at planting plus hand picking at 8 weeks after sowing (WAS), GMAP+HP8= grass mulch at planting plus hand picking at 8 WAS and F= SH3WBS+AP+HP8 application of systemic herbicide (Round up) 3 week before sowing (WBS) plus atrazine a day after sowing plus hand picking at 8 WAS.

Weedy plants recorded the highest weed parameters and lowest melon canopy cover. This is expected because weed interference is most critical and weed competition with melon was also highest in weedy plots. Thus, reduction in canopy cover and highest weed parameter is in line with the report of Ajibola and Modupeola (2014) that a weedy plot suffered comparable reduction in plant parameters (canopy cover and seed yield. Udensi and Oyeye (2016) also reported a higher weed cover and lowest melon canopy cover and attributed this to severe weed completion.

All the weed control plots produced similar weed control effects compared with weedy plots. All these are expected because of the drastically reduction in weed competition in the weed control plots.

CONCLUSION

Weeds interference significantly reduced crop yield. Reduction in weed pressure through the use of any of the weed control methods evaluated could improve melon yield for higher net return. For optimum yield of melon, farmers could use round up 3 weeks before sowing + atrazine at planting + hand picking at 8 WAS to enhance melon season-long weed suppression and guarantee profitable melon productivity.

ABSTRACT

A field study was conducted at a juvenile sweet orange orchard at the National Horticultural Research Institute Ibadan, to evaluate the effects of cover crops on weed abundance and growth of sweet orange in the orchard. The cover crop tested were; pumpkin (Cucurbita pepo L.) at 1m x 0.5m, egusi melon (Colocynthis vulgaris L.) at 1m x 0.5m , sweetpotato (Ipomoea batatas L. (Lam) at 1m x 1m, akidi (Vigna Sesquipedalis) at 50cm x 75cm, hand slashing (HS) (4 times/year) and no weeding (NW) as control. The spacing for sweet orange was 5m x 5m, with plot size of 10m x 10m. The experimental design was randomized complete block design in four replications. Data collected include ground coverage (GC), weed density, weed biomass and weed control efficiency (WCE), plant height and number of leaves. Data collected were analysed using descriptive statistics and ANOVA at $\alpha_{0.05}$. Results obtained revealed that akidi plots recorded significantly higher GC of 91.9% while the lowest (50%) was recorded from egusi melon plots at 12 WAP. Lower weed densities (5.8 and 11.8 no/m^2) were recorded from sweetpotato and akidi plots respectively, while the highest (27.5 no/m^2) was recorded from HS and NW plots. Weed biomass ranged from 122g/m^2 (akidi) to 649.0g/m^2 (NW). The WCE (%) is in the order 78 (akidi) > 72 (sweetpotato) > 71 (pumpkin) > 63 (egusi melon) > 33 (HS). Plant height ranged between 82.7 (sweetpotato) to 55.6 (egusi melon). There were no significant differences between number of leaves and number of branches.

Key words: Cover crop, weed control efficiency, ground coverage, weed suppression, sweet orange

INTRODUCTION

Cover crops are crops planted majorly to manage soil water, soil quality, soil fertility, soil quality, weeds, pests and diseases, biodiversity and wildlife in agro ecosystems (Lu *et al.,* 2000). Farmers grow cover crop types based on their own choice, needs and goals. These are largely influenced by the environmental, biological, social-cultural, and economic factors of the farming and food system within which farmers operates (Snapp *et al.,* 2005). The planting of cover crops when in combination with occasional spot slashing of shrubs, maintain a good view of interrows (Usoroh, 1991). Obiefuna (1989) reported an effective suppression of growth of weed of between 3 to 7 months when plantain was intercropped with 2,500 melons/ha and 5000 melons/ha respectively. Similarly, pumpkin and wide spreading cucurbits were found to significantly suppress weeds in arable crops in Nigeria and South Africa (Nwagwu *et al*., 2000). Michael (2011) evaluating seven cover crops for weed suppression in maize reported that weed suppression was in order akidi > Sweet potato > Melon > Water melon > Fluted pumpkin > pumpkin. The use of cover crops like melon either reduces weed seed germination or smothers the germinated seedlings and established plants. Cover crop stands with higher population density often compete well with weeds during the growth of the cover crops. This competition prevents most germinated weed seeds from completing their life cycle and reproducing. The cover crop reduces weed seed germination if they are left on the soil surface rather than ploughing into the soil as a green manure after their growth is terminated. This is because they form an impenetrable mat that block the light transmittance to the weeds (Teasdale, 1993). Moreso, as the weed seeds is germinating, they run out of stored energy for growth before building the necessary structural capacity to break through the cover crop mulch layer. This is often termed the cover crop smothering effect (Kobayashi *et al*., 2003). Cover crop permits reduction of herbicide input and help in soil fertility maintenance and erosion control (Teasdale, 1996). However, cover crops do not provide complete weed control and have to be augmented with other weed management methods.

MATERIAL AND METHODS

The experimental site was a newly established orchard planted with sweet orange var. Agege-1 budded on Cleopatra mandarin rootstock at National Horticultural Research Institute (NIHORT) Ibadan (07° 24′ 36.88″ N, 003° 51′ 16.05″ E, 213 meters above sea level). Ibadan lies in the derived savanna of South West Nigeria. The soil in the experimental area belongs to the main soil series of Egbeda (Smyth and Montgomery, 1962). They are also classified as Alfisols and Lixisols (Soil Survey Staff, 1990; Okafor, 2016).

The study was carried out in a citrus orchard planted with sweet orange var. Agege-1 budded on Cleopatra mandarin rootstock. The cover crop treatments assigned were; pumpkin (*Cucurbita pepo* L.) at 1m x 0.5m, egusi melon (*Colocynthis vulgaris* L.) at 1m x 0.5m, sweetpotato (*Ipomoea batatas* L. (Lam) at 1m x 1m, akidi (*Vigna unguiculata susp. Sesquipedalis*) at 50cm x 75cm. hand slashing (4 times/year) and no weeding (Weedy check) as control. Sweet orange seedlings were planted to a plot area of 10m x 10m (100m^2), while the spacing for sweet orange was 5m x 5 m. The cover crops were planted at the same time with the transplanting of sweet orange seedlings in the orchard. The experimental design was randomized complete block design with four replications. Data were collected on ground coverage of cover crops, weed density, weed biomass and weed control efficiency, plant height, number of leaves and number of branches.

Weed control efficiency (WCE) was calculated using;

$\mathrm{WCE}\ (\%) = \frac{\mathrm{WDWC} - \mathrm{WDWT}}{\mathrm{WDWC}} \mathrm{X}\ 100$, where WDWC = Weed dry weight in weedy check.

WDWT = Weed dry weight in the treatment (Patel *et al,* 2006). Data collected were analysed using descriptive statistics and ANOVA at $\alpha_{0.05}$.

RESULTS AND DISCUSSIONS

Significantly ($p<0.05$) higher ground coverage was recorded from sweet orange plots planted with egusi melon at 6 WAP (Fig. 1). However, at 12 WAP, sweet orange plots planted with akidi recorded significantly ($p<0.05$) higher ground coverage of 91.9%. Sweetpotato plots recorded the highest weed density at 4 WAP of cover crops and at 4 WAT of sweet orange seedlings. Akidi plots had the least weed density of 8.5 plants/m^2 which was statistically ($p<0.05$) lower when compared with no weeding plots, though not statistically different when compared with other cover crop treatments and the hand slashing plots at 12 WAP. At 16 WAP, sweetpotato and akidi plots recorded significantly ($P<0.05$) lower weed densities of 5.8 and 11.8 no/m^2 respectively (Table 1). Significantly least weed biomass (10,122g/m^2) was observed from sweet orange plots planted with akidi at 4 and 16 WAP. The highest weed biomass of 649.0g/m^2 was recorded from the no weeding plots at 16 WAP. The weed control efficiency (WCE) expressed as percentage revealed that, akidi plots recorded significantly higher (78%) WCE, and closely followed by sweetpotato plots (72%). The least WCE (33%) was srecorded from no weeding plots.

Broadleaf weeds dominated in the contribution to weed population during the study. Broadleaf weeds contributed between 34.5% (akidi) and 67.3% in no weeding plots. For grass weeds, highest occurrence of 15.3% was recorded in sweetpotato plots, while 21.8% was recorded from hand slashing plots for sedge weeds. The cover crops contributed lesser weeds with occurrence of 34.5% (akidi), 58.5% (egusi melon) for broadleaf weeds while, egusi melon and sweetpotato plots contributed 5% and 11% for grass weed respectively. Sweetpotato plots contributed least number for sedge weeds. Generally, akidi and sweetpotato plots were the least contributors to the weed population during the period of study (Figure 2). The cover crops (pumpkin, egusi melon, sweetpotato and akidi) used in this study were fast growing, attaining a ground cover of between 50 – 90% at 6 – 12 WAP, and were able to smother weeds early in the orchard. The reduction in weed biomass in cover crop plots may be attributed to early and rapid ground cover by the cover crops, thereby reducing light transmission, soil moisture and nutrient to the weeds during the growth cycle of the companion crops. This also agrees with the earlier report by Olaniyan and Fagbayide, (2005) that early and continuous canopy cover smothers weed and reduces weed/crop competition, particularly for soil nutrients, light and soil water (International Institute of Agriculture (IITA, 1985). Result on weed control efficiency also showed that the lower the weed biomass, the higher the weed control efficiency (Alamu, 2019).

At 1month after transplanting (MAT), there were no significant differences among the growth attributes of the sweet orange seedlings, while at 2 and 4 MAT, sweetpotato plots had statistically ($p<0.05$) taller plants (66.0 cm and 82.7cm) as compared with other treatments. At 2 MAT, lower number of leaves was recorded from no weeding plots. Highest number of leaves was recorded from akidi plots and was statistically ($p<0.05$) higher compared with other treatments. More number of leaves of 43.8 and 53.3 were also recorded from akidi plots at 3 and 4 MAT respectively. However, these values were higher compared with other cover crop treatments and the control. Sweet orange plots planted with akidi recorded more branches at 2 MAT, while egusi melon plots recorded more branches of 6.7 and 8.9 at 3 and 4 MAT. Other treatments had branches that ranged between 7.7 (sweetpotato plots) to 5.2 in no weeding plots. The influences of various cover crops planted (pumpkin, akidi, sweetpotato and akidi) on the performance of test crop might be complicated by factors which included their wider spread to cover the soil surface as was the case with akidi and high biomass generation from pumpkin which reduced the amount of weeds present on the field, their nitrogen fixing ability and soil water conservation due to high crop biomass that cover the surface of the soil (Alamu *et al*, 2018). Care must however be taken in making the choice of the cover crops to be used so that the competition likely to be offered by the cover crop will not have negative influence on the productivity of the main crops. Olaniyan *et al.* (2008) in their preliminary investigation, where cover crops are used for weed control in citrus orchard reported that *Mucuna pruriens* which is an aggressive climber finds its way to the crown of the trees. The authors also reported that this may lead to reduction in the area available for photosynthesis and consequently reduce the fruit yield and quality if it is not properly managed.

ABSTRACT

The efficacy of four botanicals namely: Azadirachta indica (Neem), Chromolaena odorata (Siam weed), Tithonia diversifolia (Tithonia) and rind of Citrus sinensis (sweet orange) on Cycad Aulacaspis Scale (CAS) on infested Cycas revoluta (cycad plant) was evaluated in the Floriculture garden of the National Horticultural Research Institute Ibadan, Nigeria. Cypermethrin (a synthetic insecticide), was used as positive check and distilled water as control. The treatments were applied weekly as foliar sprays for 10 weeks. CAS attack on cycad was mild on plants treated with citrus rind extracts, neem extracts and cypermethrin; average on Chromolaena and tithonia extracts treated plants and severe in the control plants. Lower damage was recorded on plants treated with citrus rind extracts (12.60%) which was not significantly different from neem extracts (15.10%) and cypermethrin (15.50%) treated plants. However, 100% damage was recorded in the control plants. Orange rind, Azadirachta indica (Neem) and Chromolaena odorata extracts could be considered and used as bioactive candidates for the management of Cycad Aulacaspis Scale.

Key words: Botanicals, Cycad Aulacaspis Scale, *Cycas revoluta*, cypermethrin, management.

INTRODUCTION

Cycad (*Cycas revoluta*) is an important horticultural plant belonging to the family Cycadaceae (Schneider *et al*., 2002). The palm is native to tropical and subtropical regions and can grow in almost any medium, including soil-less ones (Dimkpa, *et al*., 2021). It performs best in sandy, well-drained soil under full sun or partial shade but grows larger leaves in more shaded environment (Dimkpa, *et al*., 2021). It has shiny, dark green leaves which grow out into a feather-like rosette on a thick shaggy trunk (Chamberlain, 1990). Propagation of *Cycas revoluta* is either by seed or clonally by removal of basal offsets. Cycad is used for beautification and in horticultural landscape around homes, institutions, horticultural gardens and offices (Nwaobasi, 2008). Cycad as a horticultural landscape plant is among the highest rated ornamental plants in floriculture business in Nigeria with high cost benefit as reported by Sani *et al*., 2016. However, its production and commercialization is threatened with many factors among which is the infestation by the scale insect, Cycad Aulacaspis Scale (CAS). Cycad Aulacaspis scale (*Aulacaspis yasumatsui* Takagi) is a notorious pest in the family Diaspididae and attack plants in the genera, cycads (Howard *et al.,* 1999). The outbreak of the pest was first noticed in the South-south region of Nigeria in 2014 (Dimkpa *et al*., 2021), and has since spread and caused great havoc in the propagation and multiplication of the plant (Dimkpa *et al*., 2021). A recent outbreak of the pest was observed in South-west region of Nigeria in 2021 causing tremendous damage and huge loss of cycad plants both in the nursery and established landscape plants.

The insect can be transported over short distances by wind and infested plants (Hodges *et al*., 2004). Female cycad scales have a waxy covering and are white or orange in color, while the male cycad scales are orange-brown in color (Weissling *et al*., 1999; Heu *et al*., 2003). A female cycad scale lays egg within 21-35 days of hatching in warmer weather condition, hatching occurs within 8-12 days (CABI, 2018); the life cycle of cycad scale is approximately 35 days from egg to adult and average longevity is 75 days (Howard *et al*., 1999). Newly hatched scales, called crawlers, migrate to the undersides of leaflets or leaves at the base of the petiole where infestation begins. As infestation progresses, the scale insect infest the upper surface of the leaflets, the trunk, seed/cones and the roots of the plant (Heu *et al*., 2003; Howard *et al*., 1999; Weissling *et al*., 1999). Highly infested cycads are almost completely white or snow-covered which eventually turned the leaves brown and crispy making its management difficult (Dimkpa, *et* al., 2021). The damage caused by CAS on cycad plants ranges from chlorotic, yellow-brown leaves, continuous plant sap removal and finally death of the plant (Broome, 2004).

Management practices which include cultural methods (pruning of infested leaves) and the use of insecticides such as Cypermethrin, Lambda-cyhalothrin and methidathion have been adopted in minimizing the spread of this insect. However, these methods have proved not to be the best option for the control of CAS coupled with the deleterious effect of chemicals on plant and human health as well as on biocontrol agents. Therefore, the need for prompt remedial measures to reduce the spread of the insect and at the same time maintain healthy environment. The use of botanicals against diverse insect pests has been employed in pest management in recent times. Botanicals are biodegradable; they reduce environmental contamination and help in maintaining the biological diversity of organisms in the eco-system (Grange and Ahmed, 1998; Isman, 2008). This study therefore aimed at determining the efficacy of indigenous botanicals as well as proven synthetic insecticide in the management of Cycad Aulacaspis Scale (CAS) on *Cycas revoluta*.

MATERIALS AND METHODS

Experiment was conducted in the Floriculture garden of the National Horticultural Research Institute (NIHORT), Idi-Ishin, Ibadan to determine the efficacy of the extracts of indigenous plant parts and synthetic insecticide in the management of Cycad Aulacaspis Scale (CAS) on *Cycas revoluta*. Eighteen (18) potted Cycad seedlings already infested with Cycad Aulacaspis Scale were collected from the nursery in the floriculture garden. Collection of plant materials and preparation of extracts used for the study was done according to the method described by Pitan, *et al. (*2015). Fresh leaves of *Azadirachta indica* (Neem), *Chromolaena odorata* (Siam weed), *Tithonia diversifolia* (Tithonia) and rind of *Citrus sinensis* (sweet orange) were collected, rinsed with distilled water to remove any contaminant and air-dried on a flat surface in the laboratory at room temperature (27± 2ºC) until they are crispy dry. The dried Neem, Siam weed, Tithonia leaves and sweet orange rinds were milled into fine powder separately using an electric blender. From the powder obtained, 100 g of each plant sample was taken and added to 1litre distilled water (10% w/v) in separate plastic containers of 2 litres and allowed to stay for 48 hours after which the extract was vigorously shaken and carefully decanted. The decanted solutions were later passed through the process of filtration using Whatman No 1 filter paper. The filtrates aqueous extracts were taken as stock solution, stored in collection bottles and used for the experiments. Cypermethrin, a standard insecticide (1% v/v) was used as the check. Control plots without any insecticide applications were also maintained. Extracts of *Azadirachta indica*, *Chromolaena odorata*, *Tithonia diversifolia*, sweet orange rind and synthetic insecticide (cypermethrin) were applied weekly as foliar sprays for 10 weeks using a hand sprayer. Control pots without any insecticide applications were also maintained. The pots were arranged in a Complete Randomized Design (CRD) with three replicates according to the six treatments. Efficacy of the botanicals on potted plants were observed and compared with the control pots and the check. The infestation by CAS on the leaves of *Cycas revoluta* before treatment was mild (having 1 - 2 leaves infested) while damage on the plant was assessed after 10 weeks of treatment application using a modified 0-5 rating scale according to Compton (1991) below:

Infestation rating scale

0 leaf infested - No infestation; 1-2 leaves infested - mild infestation, 3-4 leaves infested - average infestation; 5 or more leaves infested - severe infestation.

Damage rating scale

0 wilted - No damage; 1-2 wilted leaves - slight damage; 3-4 wilted leaves - Average damage

5 wilted leaves – Severe damage.

Statistical analyses

Cycad Aulacaspis Scale (CAS) on the plants were scored and transformed using square-root model $\sqrt{(X + 0.5)}$ before analysis of variance (ANOVA). Damage parameters were subjected to one-way ANOVA at 5% probability level. Significant means were separated using Studentized Newman-Keuls test (SNK) with SAS 9.0 statistical package.

RESULTS

Plants used in the study were from three major families namely: Maliaceae, Asteraceae and Rutaceae. The plant parts utilized were the leaves (Neem, siam weed and tithonia) and rind (sweet orange) (Table 1). Treatments application influenced the population of the insects on the foliage and trucks of the plant as well as damage done to the plant (Table 2). Reduced snow covering on the leaves and trucks (signifying reduced CAS population) was observed on plants treated with citrus rind and neem extracts which was similar to what was observed in the cypermethrin treated plants. This was followed by siam weed extract while tithonia leaf extract recorded higher population of the insects with higher snow covering on both sides of the leaves and the truck of the plants used in the study. However, highest CAS population was observed on the control plants.

Table 1: The selected plants utilized in the study

S/N	Common name	Botanical name	Family	Part used
1	Neem	*Azadirachta indica*	Maliaceae	Leaf
2	Siam weed	*Chromolaena odorata*	Asteraceae	Leaf
3	Tithonia	*Tithonia diversifolia*	Asteraceae	Leaf
4	Sweet Orange	*Citrus sinensis*	Rutaceae	Rind

Table 2: Infestation and damage by Cycad Aulacaspis Scale on cycad plants before and after 10 weeks of treatments application

Treatment	Before treatment		After treatment	
	Infestation description	Damage description	Damage Plant (%)	Damage description
Azadiracta indica	Mild	Slight damage	15.10d	Mild
Chromolaena odorata	Mild	Slight damage	45.30c	average
Tithonia diversifolia	Mild	Slight damage	55.10b	average
Citrus sinensis	Mild	Slight damage	12.60d	Mild
Cypermethrin,	Mild	Slight damage	15.50d	Mild
Control	Mild	Slight damage	100.00a	severe

Means in the same column with the same letter are not significantly different ($p > 0.05$) using Studentized Newman Keuls (SNK).

Damage on the plants varied from mild to average (on treated plants) while the control plants were severely damaged. The infestation started from base of the petiole from where it spread to the undersides of the leaflets, this infestation progressed to the upper part of the leaves, making the leaves brownish or chlorotic and eventually become dry and dead. Lower percentage plant damage was recorded on plants treated with citrus rind extracts (12.60%) which was not significantly different from what was obtainable in neem extracts (15.10%) and in the cypermethrin (15.50%) treated plants. Of the botanicals, tithonia extracts recorded higher plants damage (55.10%). However, 100% damage was recorded in the control plants. The effect by CAS infestation was mild on plants treated with citrus rind extracts, neem extracts and cypermethrin; average on Chromolaena and tithonia extracts-treated plants and severe in the control plants.

DISCUSSION

The introduction of the different Cycad species to Nigeria is due to its beautification to the environment as well as its importance as an ornamental/horticultural plant (Nwaobasi, 2008; Chamberlain, 1990). The Cycad Aulacaspis Scale (CAS) is a major constraint to cycad production and commercialization. The invasion of CAS to cycad plants in Nigeria as reported by Dimkpa et al. (2021) has posed danger to cycad species and will cause the extinction of this ornamental/aesthetic plant and negatively affect the cycad-growing industry in the country if necessary action to forestall its effects is not drastically taken. The pest infestation began at the lower surface of the leaves with appearance of snow covering on the leaves and then the trunks which later progresses to the upper parts of the plant. Scale insects has the ability to hide deep in the crevices and roots of the plant with high fecundity and egg production rate which has made the management of the insect difficult (Marler and Moore, 2010). Application of insecticides has been the major measure utilized by florists in the management of CAS. Emshousen and Mannion (2004) reported that systemic insecticides when taken up into the leaves tissues suppress CAS populations; they persist and remain effective deterrents to the target pest.

In this study, citrus rind and neem extracts on application caused high protection to infested CAS plants resulting into lower damage in the plants as observed at the end of the ten weeks' application which was similar to effect in the plants treated with the standard check 'cypermethrin'. Likewise, reduced snow covering on the leaves and trunks (signifying reduced CAS population) was observed on plants treated with citrus rind and neem extracts which was similar to what was observed in the cypermethrin treated plants. However, highest CAS population was observed on the control plants. Weissling (1999) reported that heavily infested plants shows snow covered or heavily white-washed covering on the leaves as the rate of infestation increased. Literatures have shown that orange peels and neem extracts contain bioactive substances which cause mortality, ovicidal, repellence, residual or deterrence effect to insects. Sharaby (1988) reported reduction in egg production and inhibition of egg laying in the potato tuber moth, *Phthorimaea operculella* (Zell.) when moths of either sex were exposed to orange peel extracts. Similarly, Neem extracts had been reported to have adverse effects on survival, fecundity, development and oviposition of insect pests (Charleston *et al*., 2006). Azadirachtin the active ingredient in neem has been found to suppress the activity of ecdyson (juvenile hormone) when in contact with the larvae thereby preventing moulting which eventually lead to the death of the larvae (Seljasen and Meadow, 2006).

As highest CAS population was observed on the control plants in this study, a corresponding increase in damage on the cycad plants was observed. This caused some parts of the leaves to become chlorotic, turned brown, dry with eventual destruction and death of the plants. This observation was similar to report by Heu et al. (2003) that as a result of increased density of the CAS pest, damage resulted into the leaves turning brownish and dried off. CAS sucks sap of the host which resulted into chlorotic yellow-brownish coloration of the leaves preventing photosynthetic activity in the plant which resulted into retarded growth and destruction of the entire plant. The chlorotic coloration of the leaves after infestation as reported by Muniappan *et al*. (2012) was as a result of the toxic substance in the saliva secreted and injected by the scale insect into the plant during the process of feeding.

The effect of CAS infestation on Cycad plants treated with citrus rind and neem extracts was mild; average on Chromolaena and tithonia leaf extracts but severe on the control plants. Damage on the applied plants varied from mild to average and to severe as described by Compton, (1991).

CONCLUSION

Cycad Aulacaspis Scale is a very destructive pest which is of economic importance to ornamental plants especially cycads. Management measures using botanicals can be effective with several applications. Citrus rind and neem extracts are natural plants products that are non-toxic, environmentally safe to human and other beneficial organisms and can be used as substitute to toxic chemical insecticides which has been the major control measures used by florists.

ABSTRACT:

The study was conducted at Institute for Agricultural Research (IAR) horticultural garden under irrigation in two dry seasons (2019 and 2020). The region is located at Latitude11^{0}11^{1}N and Longitude7^{0}38^{1}E. The research was conducted to evaluate the cost of plant protection using two microbial pesticides: Streptomyces avermitilis (Emamectin benzoate as active ingredient) and Beauveria bassiana, two botanical oil extracts: Karanjin from Karanja (Pongamia glabra) and Azadirachtin from Neem (Azadirachta indica), one synthetic insecticide: Cypermethrin + dimethoate (Lion Guard EC with Cypermethrin 3% and dimethoate 25%) which served as standard check against S. calamistis. The treatments involved two sweet corn varieties; Sweet Corn Yellow, Sugar King F_2 and a non-sweet maize variety; SAMMAZ 52 (Pro-vitamin A maize variety) and also the five (5) pesticides with untreated control laid out in a Randomized Complete Block Design (RCBD) in split plot with three replications on a plots size of 9m^2 (3 m x 3 m). The study showed the profitability of using the botanical extracts (with cost benefit ratio of 1:12 for Azadirachtin and 1:6 Karanjin) and microbial pesticides (with cost benefit ratio of 1:15 for Emamectin and 1:17 for B. bassiana) in the management of S. calamistis on sweet corn.

Key words: Karanjin, Emamectin, Sweet corn, Artificial Infestation

INTRODUCTION

Sweet corn (*Zea mays* var. saccharata L.) also called sugar corn and pole corn is a hybridized variety of maize with high sugar content. It is cultivated for human consumption and is a raw or processed material of the food industry throughout the world. It is popular with the consumer for its unique taste, pleasant flavour and sweetness. Sweet corn contains 5-6% sugar, 10-11% starch, 3% water soluble polysaccharides and 70% water, besides moderate levels of protein and vitamin (yellow varieties) and potassium (Oktem and Oktem, 2005). Sweet corn is one of the six major types of corn, the others being dent corn, flint corn, pod corn, popcorn, and flour corn (Campbell, 2013). Unlike field corn varieties, which are harvested when the kernels are dry and fully mature (dent stage), sweet corn is picked when immature (milk stage) and can be harvested in 75-80 days after planting and eaten as a vegetable, rather than grain (Schultheis, 1994). In Nigeria, most of the maize varieties are eaten green (either boiled, cooked or roasted) (Sani *et al.,* 2013). A gross profit of N 840,521 ($ 1= N 150) and benefit-cost ratio of 1.51 was reported by Sani *et al.* (2013) on sweet corn production which highlights its profitability and potential for high income earnings.

MATERIALS AND METHODS

The cost benefit analysis was carried out to see how economical is the use of the pesticides in controlling *S. calamistis* in sweet corn production using methods described by Shabozoi *et al.* (2011). Cost: benefit ratio is an indicator of the relative economic performance of the treatments and a ratio of more than one indicates the economic viability of the treatment compared with the control treatment.

a) **Cost of Neem oil extract Lha^{-1} (N)=** Volume Lha^{-1} x Price L^{-1}
b) **Cost of Karanja oil extract Lha^{-1} (N)=** Volume Lha^{-1} x Price L^{-1}
c) **Cost of Cypermethrin + Dimethoate) Lha^{-1} (N) =** Volume Lha^{-1} x Price L^{-1}
d) **Cost of Emamectin benzoate Kgha^{-1} (N)=** Quantity in Kg ha^{-1} x Price Kg^{-1}
e) **Cost of *B. bassiana* Kgha^{-1} (N) =** Quantity in Kg ha^{-1} x Price Kg^{-1}

f) **Total income of fresh Sweet corn (Nha^{-1}) =** Total Fresh yield in Kg ha^{-1} x Price Kg^{-1}

g) **Net Benefit (Nha^{-1}) =** Total income – Cost of plant Protection

h) **Benefit of spray (Nha^{-1}) =** Net benefit of spray – Total income of untreated control

i) $$\text{Cost: Benefit ratio} = \frac{\text{Benefit of sprayed treament}}{\text{Cost of plant Protection}}$$

j) $$\text{Return on invetment} = \frac{\text{Total income of treatment}}{\text{Cost of plant Protection}}$$ (Shabozoi *et al.,* 2011)

RESULTS AND DISCUSSION

The microbial pesticides, botanical treatments and the synthetic insecticide were superior financially compared to the untreated control in which sweet corn were heavily attacked by *S. calamistis* (Table 1). Accordingly, treatments other than the control had higher yields which resulted in revenue that exceeded the cost of the plant protection. The cost of plant protection using Cypermethrin+Dimethoate was higher than all of the biopesticides and the botanicals. The best cost: benefit ratio of 1:17 was for *B. bassiana* treatment. It was followed by Cypermethrin+Dimethoate with a cost: benefit ratio of 1:15. Plots sprayed with Emamectin had a cost: benefit ratio of 1:15 while plots sprayed with Azadirachtin had a cost: benefit ratio of 1:12 and Karanjin had cost: benefit ratio of 1:6.

Table 1: Cost Benefit Analysis of the Pesticides used against *S. calamistis*

Variables	Neem oil extract	Karanja oil extract	*Beauvaria bassiana*	Emamectin benzoate	Lion guard	Untreated control
A) Total yield (ton ha^{-1})	8.46	7.22	9.79	9.52	11.43	6.49
B) Total income (₦ ha^{-1})	436,000	312,000	569,000	542,000	733,000	139,000
C) Cost of plant protection (₦ ha^{-1})	15,000	10,000	18,500	19,000	30,000	0
D) Net benefit (₦ ha^{-1}) (B-C)	421,000	302,000	550,500	523,000	703,000	239,000
E) Benefit over untreated control (₦ ha^{-1})	182,000	63,000	311,500	286,000	464,000	-
F) Cost-Benefit ratio (E/C)	1:12	1:6	1:17	1:15	1:15	-
G) Return on investment (B/C)	12.1	31.2	30.8	28.5	24.4	-

In this study, the botanicals Azadirachtin and Karanjin gave the cost benefit ratios of 1:12 and 1:6 respectively, while Emamectin and *B. bassiana* gave the cost benefit ratios of 1:15 and 1:17 respectively. The cost: benefit ratios of botanicals and microbial pesticides calculated in this study are similar to those obtained by Patel *et al.* (1997), who obtained a ratio of 1:14 and 1:13 for botanical (neem extract) and synthetic insecticide (endosulfan) respectively in managing insect pests of pigeon pea. This is because this study analysed only the cost of plant protection and calculated the cost: benefit ratio based on the income of the control treatment. Amoabeng *et al.*, (2014), also reported cost: benefit ratios of between 1:29 and 1:4 for the botanicals Siam weed and tobacco on cabbage pest indicated that, they were biologically effective and resulted in significant return on investment in plant protection. The cost benefit ratio is highly dependent on the commodity price at any particular period and the exchange rate. At the time of this study the exchange rate of Dollar to Naira 1:380 which is not good, but still, not many crops would give that return due to the expensive nature of sweet corn.

CONCLUSION

The study also showed the profitability of using the botanical extracts (with cost benefit ratio of 1:12 for Azadirachtin and 1:6 Karanjin) and microbial pesticides (with cost benefit ratio of 1:15 for Emamectin and 1:17 for *B. bassiana*) in the management of *S. calamistis* on sweet corn.

ABSTRACT

Production of simulated cashew meat as a substitute for both meat consumers and vegetarians has come as a way of adding value to wasting cashew apple that has become menace in our cashew farms. Current research on plant-based meat alternatives (PBMAs) is on the increase in food and research communities. However, little is known about cashew apple meat. Despite its high protein content and even low cost, cashew apple remains underutilized in human foods. Consequently, the production of simulated cashew meat could be a way of maximizing cashew apples that has constituted nuisance in most cashew farms. Therefore, this study evaluated the simulated cashew apple meat-like product for its organoleptic acceptability and physicochemical quality. The meat-like substance developed from cashew apple was very similar to the conventional dried meat. Notably, no significant difference was observed when the sensory analysis of the simulated cashew apple meat was compared with that of the conventional dried meat.

Key words: Cashew apple meat, vegetarians, substitute, consumers

INTRODUCTION

Throughout history, humans have considered meat to be an essential part of their diet (Stanford and Bunn, 2001). The consumption of meat has been key for human evolution as it has been linked to the brain growth and development within prehistoric *Homo sapiens* (Williams and Hill, 2017). Globally, beef, pork, and chicken products are the highest in demand, with the United States and Australia topping the charts for the highest annual meat consumption (Ritchie, 2019). Due to an increase in global population and rapid economic development, the last two decades have seen a 58% growth in the global demand for meats. By 2018, approximately 320 tonnes of meat was consumed worldwide and it is predicted that the market will expand 15% by 2027 (OECD/FAO, 2018). However, the inefficiencies of meat production compared to crop harvesting and the negative impacts from the consumption of conventional meats on human health have become topics of concern in recent years (Godfray *et al*., 2018; Marinova and Bogueva, 2019). Due to these increasing concerns, food industries are looking for ways to introduce healthier meat alternatives made from non-animal proteins, but with similar appearances, mouthfeel, and smells to consumer markets (Malav *et al*., 2015). Despite the fact that plant-based meat alternative (PBMA) has become one of the current hottest topics in the academic community, and thus original research articles and review papers outlining different emphasis on this topic have been published (Kumar, 2016). Nevertheless, the research on cashew meat as plant-based meat alternatives (PBMAs) is scanty in literature.

Cashew (*Anacardium occidentale, L*) is a tropical and edible fruit whose genus name *Anacardium* which means "shaped like heart" is derived from the shape of cashew apple. Cashew apple is the pseudo-fruit connected to the real fruit which is cashew nut (Zepka and Mercadante, 2009). Cashew apple is characterized by its fibrous nature and a unique astringent smell. The utilization of this apple is mostly for the production of its juice and wine. The residue made of the skin and the husk called bagasse is frequently used for animal feed or even allowed to waste away. The residue has a dark yellow colour, a fibrous aspect, and a typical astringent aroma due to the presence of tannins which could be a limiting factor for the acceptability of the cashew apple and the juice, especially in foreign countries (Michodjehoun-Mestres *et al*., 2009). Regarding to the use of cashew apple for meat, there are not many researches mentioned. This study therefore focused on the production of a meat-like substance from cashew apples as an alternative source of meat for the vegetarians.

MATERIALS AND METHODS

Cashew apples were collected during its peak season from Cocoa Research Institute of Nigeria, Ibadan and simulated into meat production, the processing was done through the use of different drying techniques to produce cashew apple meat. The biomass composition of the simulated cashew meat was estimated. The products were subjected to organoleptic appraisal and physicochemical analysis.

RESULTS AND DISCUSSION

The result for the biomass composition of the cashew meat (Table 1) revealed that the plant-based meat alternative has high lignin, cellulose and hemicellulose compositions. Also, the organoleptic appraisal of the cashew meat described in Table 2 shows that the cashew apple meat was well-accepted and that there is no significant difference between the simulated meat and the standard (cow-meat). Thereby, suggesting a probable favourable competition between the cashew meat and the conventional dried meat. Apparently, cashew meat substitute has the potential to compete with commercial meat analogues, thereby adding value to the cashew industry.

Table 1. Biomass Composition of Cashew Meat

Composition	%
Cellulose	34.21±31
Hemicellulose	26.23±28
Lignin	36.24±15
Ash	3.32±35

Table 2. Sensory Evaluation of Cashew Meat

Attributes	Samples			
	DC	SM	DM	CM

Taste	8.52	6.12	8.62	8.54
Flavor	7.63	6.42	7.82	7.22
Texture	8.21	6.12	8.64	8.62
Overall Acceptability	8.14	6.33	8.66	8.42

Key
Dc – Dried chicken, Sm – Dried soymeat, Dm – Dried meat, Cm – Dried cashew meat

Moreover, in the physicochemical characteristics presented in Table 3, the plant-based meat protein's composition was revealed to be 18.71%. Interestingly, this finding is in agreement with the reports of Asgar and Wild that the main component of meat analogues is protein (Asgar *et al*., 2010; Wild *et al*., 2014). The cashew meat is also very rich in crude and non-digestible fibers (14.32% and 82.1% respectively) thus, suitable for good health.

In general, plant-based dietary patterns are associated with health benefits. Vegetarian diets (meat-free dietary patterns) are associated with reduced risks of many health conditions. Vegetarians have lower incidence of type 2 diabetes, obesity, coronary heart diseases and other non-communicable diseases, thus having greater life expectancy (Le and Sabate, 2014; Dinu *et al*., 2017). The Academy of Nutrition and Dietetics (formerly the American Dietetic Association) has recognized that a well-planned vegetarian diet is healthful and nutritionally adequate, being appropriate for human growth and development. Meat-free diets are suitable not only in the prevention but also in the treatment of many diseases (American Dietetic Association, Dietitians Association of Canada (2003); Melina *et al*., 2016; Fresan and Sabate, 2019).

Table 3: Physicochemical Characterization of Cashew Meat

Parameters	Composition %
Moisture	9.33
pH	4.21
Soluble solids (°brix)	0.00±0.01
Reducing sugar	0.54±0.02
Crude protein	18.71
Crude fiber	14.32
Non-Digestible fiber	82.1

CONCLUSION

Developed cashew apple meat has been widely accepted as it has come to add to our satiety value. It is good news to the vegetarians who can as well enjoy their meals with meat from plant origin. Conclusively, in our present societies in Nigeria where daily meat consumption is the social norm, aspiring to drastically reduce meat consumption is a challenging endeavor. More research is needed to better understand the cultural and socioeconomic factors that influence change in dietary patterns.

ABSTRACT

Proximate analysis, phytochemical and mineral compositions of Cola nitida are some of the commonest and basic nutritional investigations carried out on kola nuts in Nigeria. Overtime, several researchers from some part of Nigeria reported different values of proximate analysis, phytochemical and mineral constituents of Cola nitida. In the present study, we analyzed some of the data obtained by these authors on proximate, phytochemical and mineral constituents of kolanuts in Nigeria using data mining software to get a secondary data. This secondary data enabled proper comparison and general overview of Cola nitida's proximate and mineral distribution from some States in Nigeria. In this regard, the result from the proximate analysis's secondary data apparently revealed that the Cola nitida from all the towns reviewed except for Benin in Edo State have high carbohydrate contents. Moreover, other attributes such as ash, lipid and protein contents of these kolanuts are generally low. However, Ilorin in Kwara State has the highest moisture content and the lowest protein content. Sagamu in Ogun State and Ado in Ekiti State have the highest protein values of 15.24±0.58 (% wt/vol) and 15.40 (% wt/vol) respectively. Although the Benin kolanuts have low proximate characteristics however, they are rich in phytochemical constituents especially alkaloids, saponins and tannins. Correspondingly, the Cola nitida in Benin have the highest mineral composition.

Key words: *Cola nitida*, proximate, mineral composition, phytochemicals

INTRODUCTION

Kolanut is an African plant having about 125 species which are all indigenous to Tropical West Africa. Among these species is *Cola nitida*, a kolanut with only two cotyledons. The cultivation of *C. nitida* actually began in Nigeria in the 19th century (Asogwa *et al*., 2006). Kolanut, a masticatory stimulant is an edible fruit, with tremendous medicinal, religious and social values. Although, there is increasing demand of kolanut for its usage in pharmaceutical and food industries for production of drugs, wines, chocolates and non-alcoholic beverages (Beattie, 1970; Ogutuga, 1975; Jarvis, 2002; Dah-Nouvlessounon *et al*., 2015). However, the medicinal importance of kolanuts stems from their pharmacological properties and active chemical constituents such as caffeine, theobromine and kolatin which is somewhat similar to those of coffee and cocoa (Atanda, 2011).

Over the years, the bioactive, mineral and nutritional characterization of kolanuts especially *C. nitida* are often investigated via basic researches such as proximate analysis and phytochemical screening of the kolanuts. Incidentally, several scientific researches have reported different mineral, proximate and phytochemical constituents of *C. nitida* across Nigeria. In spite of the fact that there is extensive research into examining the proximate and phytochemical composition of *C. nitida* in some part of Nigeria nevertheless there is little or no reports on the comparison of these phytoconstituents across Nigeria. Hence, this present study aims at reporting the comparative studies on proximate, mineral and phytochemical constituents of *C. nitida* in some parts of Nigeria.

MATERIALS AND METHODS

A secondary data generated via graph pad prism software from the primary data of proximate, mineral and phytochemical constituents' analysis of *C. nitida* from different research authors in some part of Nigeria were used as itemized below.

- Proximate analysis of *C. nitida* from Benin (Dah-Nouvlessounon *et al*., 2015; Okwunodulu and Ukeje, 2018), Ibadan (Jayeola, 2001), Minna (Ajai *et al*., 2012), Ilorin (Odebunmi *et al*., 2009), Umudike (Okeke, 2015), Ado Ekiti (Dewole *et al*., 2013), Ipetumodu (Adeniyi *et al*., 2017) and Sagamu
- Mineral compositions of *C. nitida* from Benin (Dah-Nouvlessounon *et al*., 2015; Okwunodulu and Ukeje, 2018), Minna (Ajai *et al*., 2012) and Ilorin (Odebunmi *et al*., 2009).

- Phytochemical constituents of *C. nitida* from Benin (Dah-Nouvlessounon *et al*., 2015; Okwunodulu and Ukeje, 2018), Ibadan (Jayeola, 2001), Umudike (Okeke, 2015), Ado Ekiti (Dewole *et al*., 2013) and Akure.

RESULTS AND DISCUSSION

The proximate and mineral analysis of *C. nitida* has been well-studied in many parts of Nigeria. Apparently, the proximate analysis of *C. nitida* as shown in Figure 1 revealed that the kolanuts in most of the towns considered (Benin, Ibadan, Minna, Ilorin, Umudike, Ado and Ipetumodu) are very rich in carbohydrates (CHO) with Ibadan kolanut having the highest CHO while Benin kolanut has low CHO content. Moreover, the moisture contents of kola nuts from Ibadan, Ilorin and umudike are significantly higher than others and this could be attributed in part to the tropical lowland rainforest areas where these kolanuts are grown. In fact, as depicted in Figure 1, Benin and Sagamu kola nuts are generally low in their proximate analysis. However, there is an overall low level of ash, lipids and proteins of *C. nitida* in the towns considered. The low ash and fat contents of these kola nuts is in agreement with earlier report that most tropical fruits have low ash content and are neither rich sources of fats (Ogutuga, 1975).

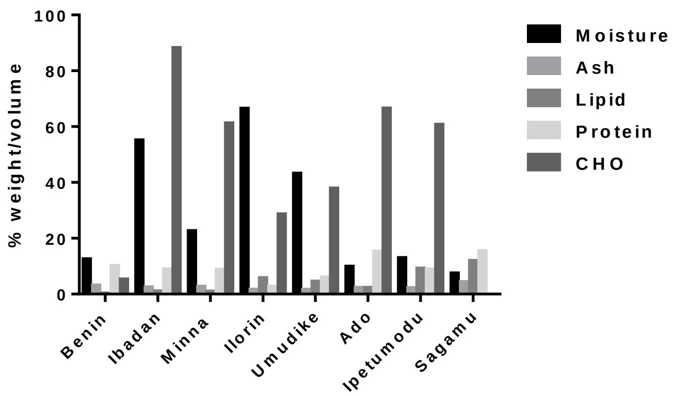

Figure 1. Proximate compositions of *Cola nitida* seeds from some parts of Nigeria

Moreover, kola nuts have been reported to contain traces of essential minerals. Some of these minerals act as sources of macro and micro nutrients needed for the growth, development and metabolic activities of man (Odebunmi *et al*., 2009; Adeniyi *et al*., 2017). Figure 2 markedly revealed the mineral analysis of *C. nitida* from Benin, Minna and Ilorin. It was observed from the result that the Benin kola nuts are richer in calcium, zinc, iron and magnesium than the kola nuts from Minna and Ilorin.

The Phytochemical analysis of the *C. nitida* obtained from investigated towns in Nigeria is presented in Figure 3. Phytochemical analysis is an analysis that reveals the rich bioactive constituents present or absent in kolanuts. These constituents are secondary metabolites such as Alkaloids, Tannins, Flavonoids, Saponins, phenols and Anthraquinones consequently signifying the biological importance and medicinal potentials of the nuts. In this regard, the *C. nitida* from Ado, Benin and Akure has considerable amount of tannins. While the Umudike kolanuts generally have low phytochemical constituents, nevertheless the *C. nitida* from Benin and Ibadan are significantly rich in alkaloids. In addition, Benin kola nuts are relatively high in saponins when compared with the saponin contents of kola nuts from other towns.

Summarily, it is apparent from this study that the distribution of proximate, mineral and phytochemical properties of *C. nitida* in some parts of Nigeria varies from one location to the other.

ABSTRACT

This study investigated the effect of germination periods on nutritional and antinutritional components of grain amaranth seeds processed into flours. The grain amaranth flour was evaluated at varying germination periods (24hrs, 48hrs and 72hrs) under room temperature (28 ± 0.1°C) for their proximate, minerals and antinutrients. It was found that the periods of germination varied influenced the concentration of various nutrients and antinutrient parameters considered. The highest protein content for amaranth flours after 24hr germination period was (17.37%) which was significantly higher(p<0.05) compared to 48hr (16.73%),72hr (16.05%) and ungerminated amaranth flour (16.06%) which served as control. The values of antinutrient factors which include tannins ranged between (0.154-0.933mg/g), oxalate (0.196-0.520mg/g), phytate (0.210-0.813mg/g) and trypsin inhibitor (0.446-0.856TIU/mg). There was varying degree of reductions in the concentration of antinutrients in amaranth flour across the periods of germination which were significant compared to ungerminated amaranth flour. The phytate in ungerminated amaranth grain flour was (0.813mg/g). This significantly (p<0.05) reduced to (0.286mg/g), (0.226mg/g) and 72hr (0.210mg/g) after 24hr, 48hr and 72hr germination respectively. The reduction in phytate concentration has been attributed to activation of phytase enzyme during germination which breaks down phytic acid thus reducing their concentration.

Key words: Grain amaranth, flours, germination, antinutrients, Phytate.

INTRODUCTION

Diversification of diets in Africa with underutilized and underexploited food crops such as grain amaranth present a viable option and sustainable alternative through which malnutrition problem could be fought through provision of basic and essential nutrients needed for optimum body functions and development, particularly for rural and poor urban households in developing countries where malnutrition is severe and continue to be a big a threat due to its associated consequences (FAO, 2015; FAO,2020; Aderibigbe *et al*., 2020). Amaranth is one such crop which has high potentials to act as alternative food grain in most parts of the world. It is one of the few plants whose leaves are eaten as a vegetable while the grains (seeds) used in the same way as cereals and consumed in various parts of the world.

The amaranth grains are rich in essential amino acid and their amino acid composition is better balanced than in most cereals. The consumption of amaranth grains (seeds) along with other cereals which are low in essential amino acids could be needed to provide a "balanced" source of protein. Amaranth is a good source of riboflavin, vitamin E, calcium, magnesium and iron minerals (Akin-Idowu *et al*., 2017).

Although, grain amaranth as pseudo cereal is rich in essential nutrients needed for growth and development but the interaction between its available basic nutrients and antinutrients to form complexes within food matrixes reduces the bioavailability of its useful and essential nutrients (Njoki *et al.*, 2015). The phytate and trypsin inhibitor in grains for example lowers the sufficient release of minerals and reduces protein bioavability. However, some traditional food processing methods such as soaking, fermentation and germination which also known as malting has been suggested as capable of reducing the antinutrients thereby improving the bioavailability of micronutrients in plant-based diets. Therefore, this study aimed at evaluating the effect of different germination periods as a pretreatment for nutrient improvement in amaranth grains flour.

MATERIALS AND METHODS

Raw material collection

Grain amaranth (*amaranth cruentus*) seeds was collected from the experimental field of National

Horticultural Research Institute (NIHORT), Idi-ishin, Ibadan, Nigeria.

Preparation of germinated grain amaranth flours

The germinated amaranth grain flours were prepared as described by (Sara and Valérie, 2016). The grains were sorted, washed thoroughly and soaked in water at grain to water ratio of 1:3 (w/v) for 24h at room temperature (28±0.1). The water was allowed to drain and grains wrapped in a white cloth and kept at varying periods of 24hrs, 48hrs and 72hrs to germinate. After germination, sprouted grains were thoroughly rinsed in distilled water, then dried at 45–50°C and milled using (Marlex excella electric grinder, model 750). The flour was made into fine powder using a sieved with 0.25mm diameter and stored in air-tight containers.

Analysis of samples

Proximate compositions of samples were determined using (AOAC, 2005). The phytate by (Wheeler and Ferrel, 1971). Oxalate by (Chinma and Igyor, 2007). Tannin by (Ijarotimi 2012) and Trypsin inhibitor determination by (Panta, 2017).

Statistical analysis

The data were analyzed using IBM Statistical Package for the Social Sciences (SPSS) 22. The means and standard deviations of samples in triplicate were calculated. The analysis of variance (ANOVA) was performed to determine significant differences between the means using Duncan test. Statistical significance was set at P<0.05)

RESULTS AND DISCUSSION

The effect of germination periods on proximate composition of amaranth grain flour

The result of proximate composition as influenced by different germination periods are presented in Table 1. The protein content (17.37%) after 24hrs germination was significantly (P<0.05) higher than 48hrs (16.05%), 72hrs (16.73%) and ungerminated flour (16.08%). Germination has been reported to increase protein, this however depend on type of grains (Laxmi *et al*., 2015). The increase in protein during germination was attributed to the release of packed protein in seed structure, when enzymes such as α-amylase break down the starch granules. The activation of protease enzyme during this process detaches protein attached to sugar molecules. Other factor implicated is the occurrence of protein synthesis (Chauha *et al*., 2015). It was opined that the increase or otherwise in protein concentration during germination is a function of the balance between protein synthesis and hydrolysis. The (Bożena and Dariusz, 2012) observed a higher protein concentration (7.40%) after 24hrs germination compared to 48hrs (6.83%) during the germination of bean seed. (Fabiola *et al.,* 2019) reported that a short germination of 24hr is enough to effect significant changes in the nutritional properties of amaranth when he studied the germination effect on nutritional changes in two amaranth species (*Amaranthus quitensis* and *Amaranthus caudatus*).

Table 1. Effects of germination period on proximate composition on grain amaranth flour

samples	Moisture (%)	Protein (%)	Fat (%)	Ash (%)	Fibre (%)	CHO (%)
Control	8.41±0.01[a]	16.08±0.12[c]	5.75±0.01[d]	2.19±0.01[d]	4.37±0.01[c]	63.28±0.10[b]
24hr germination	7.20±0.01[d]	17.37±0.01[a]	6.75±0.05[c]	2.65±0.01[ab]	4.62±0.01[b]	62.46±0.01[d]
48hr germination	7.51±0.01[c]	16.73±0.01[b]	7.64±0.01[b]	2.47±0.01[c]	4.18±0.02[d]	63.18±0.11[c]
72hr germination	7.70±0.46[b]	16.05±0.56[cd]	8.13±0.20[a]	2.69±0.02[a]	4.97±0.01[a]	63.61±0.11[a]

Values are means ± standard deviation of duplicate determinations. Values with the same superscripts in the same column are not significantly different at P < 0.05.

Proteins are major functional and structural components of all the body's cells and when intake is too low, growth during childhood is compromised (Alles *et al.,* 2014). Adequate protein ingestion is needed to elicit muscle protein synthetic response; this could be achieved by consumption of protein rich food such as germinated grain amaranth for optimization of dietary protein intake, failure of which can result into low physical activities. some proteins are hormones which are chemical message that assist in cell to cell communication. The energy value of germinated amaranth flour after 24hrs germination period (379.61kcal/100g) is significantly ($P<0.05$) higher than 48hrs (375.03mg/100g) and 72hrs (374kcal/100g) respectively. Energy is needed by living beings to perform all vital and necessary body functions. Energy is utilized partly for mechanical work performed by muscles. Diet given in early childhood is marked by high nutrient needs that include notably protein and energy (Dewey, 2013) therefore, quantitative assessment of energy value of raw material to be used in food formulation is very important. The germination of amaranth grain for 24hrs could improve energy value thus make the amaranth grains a good source of complementary food for energy requirement.

The effect of germination periods on antinutrient factors

The result in Table 2 summarizes the effect of different germination periods on antinutrients that includes tannins, phytate, and oxalate and trypsin inhibitor. The value for tannins was between (0.154-0.933mg/100g), oxalate (0.196-0.520mg/100g), phytate(0.186-0.813mg/100g) and trypsin inhibitor(0.446-0.856TIU/mg) respectively. There was a varying degree of reduction in the concentration of antinutrients in germinated amaranth flours across the germination periods. The result showed that level of phytate in ungerminated grain of amaranth flour (0.813mg/100g) was significantly higher ($p<0.05$) compared to what obtained after 24hr (0.286mg/100g), 48hr (0.226mg/100g) and 72hr (0.210mg/100g) respectively. There was a significant reduction in phytate concentration from 0.813mg/100g to 0.286mg/100g) which represents a 64% reduction after 24 hr germination. A similar reduction in phytate concentration after 24hrs germination in pearl millet was observed by (Khetarpaul and Chauhan, 1990). The anti-nutritional factors are secondary metabolites that do affect the nutritional value of foods (Nkhata *et al.,* 2018). However, their concentration can be reduced by the use of traditional food preparation techniques such as soaking and germination (malting).

Table 2: Effects of germination period on antinutrients composition amaranth grain flour

Samples)	**Tannin (mg/100g)**	**Oxalate (mg/100g)**	**Phytate (mg/100g)**	**Trypsin Inhibitor(TIU/mg)**
Control	0.933±0.12[a]	0.520±0.52[a]	0.813±0.81[a]	0.856±0.85[a]
24hr germination	0.273±0.05[b]	0.223±0.21[b]	0.286±0.18[b]	0.460±0.46[c]
48hr germination	0.163±0.05[c]	0.213±0.22[c]	0.226±0.21[c]	0.443±0.59[b]
72hr germination	0.154±0.33[cd]	0.196±0.19[d]	0.210±0.23[cd]	0.426±0.44[d]

Values are means ± standard deviation of duplicate determinations. Values with the same superscripts in the same column are not significantly different at $P < 0.05$.

CONCLUSION

Anti-nutritional factors in foods are responsible for reduction in bioavailability of essential nutrients desirable for proper development and good health. The application of germination technique to reduce anti-nutritional in amaranth grains to induce improvement in concentration of protein and other nutrients could be a good intervention at household level for nutrition security. This study shows that 24hrs germination provided the optimum period for significant improvement in protein value.

ABSTRACT

This study was based on desk review comparison of seven journals on proximate, selected phytochemical and mineral constituents of cashew nuts sourced from Abia, Adamawa, Imo, Enugu and Kogi States in Nigeria. Cashew nuts sourced from Enugu and Adamawa States recorded high carbohydrate content compared with those sourced from other locations (Abia, Imo, Kogi) but recorded a low crude fat content when compared with the ones sourced from other states. Nuts from Enugu State recorded high moisture content compared to others which show not much significant differences. Protein content of cashew nuts from Enugu, Kogi and Adamawa states were relatively low compared to those from other locations. Crude fibre content of nuts from Isiukwuato, Abia State was relatively high compared to those from other states. Ash content compared favourably well across all states except for Kogi where it was relatively low. In Imo State, tannin content of nuts was found to be lower than those sourced from Abia and Enugu states. Alkaloid in cashew nuts from Enugu State was found to be relatively low compared Isiukwuato in Abia and Imo State. Levels of potassium, magnesium and phosphorus of nuts from Enugu State were relatively lower compared to nuts from other states (Imo and Abia).

Key words: Cashew Nuts, Proximate, Phytochemical, Mineral

INTRODUCTION

Cashew plant (*Anacardium occidentale*) is said to be a tropical plant with its origin as the Latin America, specifically North-Eastern Brazil (Dike *et al.,* 2012). The tree belongs to the family *Anacardiaceae* with about 75 genera and 700 species among which the economically known ones are mango and pistachio (Nakasone and Paull, 1998). Cashew tree of all domestically grown tropical fruit trees is the most widely domesticated food plant ahead of mango and pawpaw trees (Daramola, 2013). The nuts are usually dry, hard-shelled and do not split on maturity hence, the seeds are not released (Olife *et al.,* 2013). The nut is about 3cm long and is kidney shaped (Joker, 2003) and the tree is said to be drought resistant and grows well in a variety of soils with tropical climatic condition (Akinhanmi, 2008).

Introduced in Nigeria in the 15th Century, by the Portuguese, cashew nuts are used as a form of afforestation scheme in a bid to control the rate of erosion in Eastern Nigeria (Ohler, 1979) and its cultivation was extensively practiced in Nigeria in the early 1950s which has since increased to about 30 folds between 1990 and 2012 (FAO, 2013a) with Nigeria being one of the largest producers (FAO, 2013b). Planted by directly placing the seeds in the field or by budding, grafting or marcotting (Joker, 2003), cashew plants have variations in physical characteristics such as growth pattern, quality of crop, yield of fruits, colour of apple and size of the nut (Adeigbe *et al.,* 2015). The nuts are of major economic importance hence, special interest in them. Cashew nuts can be processed using several techniques which include: cleaning, soaking, roasting, shelling, drying and peeling (Joker, 2003; Esenwah and Ikenebomeh, 2008). Usually taken as snacks, the cashew nuts are roasted to enhance their flavor (Raji *et al.,* 2011) perhaps because of its nutritional quality such as dietary fiber and health promoting phytochemicals (Olife *et al.,* 2013) which are said to be protective against diseases and sometimes ageing (Burns *et al.,* 2001). Many plants may have generalized standard values of proximate, phytochemical and mineral constituents but due to some factors such as environmental and agronomic conditions; harvest and food processing operations; storage factors; soil types and seasonal change (Figueiredo *et al.,* 2001), these properties may differ especially when sourced from different locations, hence this desk review. The review compares the proximate, some phytochemical and mineral constituents of cashew nuts from selected locations in Nigeria to support these claims and suggest insight on possible panacea.

MATERIALS AND METHODS

A total of seven (7) journals: Nkwocha *et al.,* 2020, Hayatuddeen *et al.,* 2019, Okoroh and Onuoha, 2019, Akujobi *et al.,* 2018, Olalekan-Adeniran and

Ogunwolu, 2018, Okonkwo and Ozoude, 2015, Nwosu *et al.,* 2014 were considered for this desk review cutting across five (5) different states of Nigeria based on their source of cashew nuts. The results of their proximate analysis, some selected phytochemical and mineral analysis were compared based on the state they were sourced from. The results of which were then represented with a bar chat plot for explicit discussion.

RESULTS AND DISCUSSION

Of all the six locations, the moisture content of cashew nuts sourced from Nsukka is the highest (22.49%) and this can be as a result of seasonal change or weather situation with respect to the humidity and temperature of the location and also the post-harvest methods employed which can be of influence not only on the moisture content but also on some other qualitative properties while the moisture contents of cashew nuts sourced from other locations compared favourably well with one another (Fig. 1). The conditions suggested above may also responsible for the low protein content recorded in cashew nuts sourced from Nsukka, Geriei and Ochaja in Enugu, Adamawa and Kogi States respectively (12.60%, 14.26%, 17.37% and 18.25%) with that of Nsukka been the lowest. The protein content (ranging from 24.78% - 34.0%) of nuts from other locations are considerably higher and compared favourably well with some standards such as soybean. This may be as result of weather situation in the area of cultivation which might alter some metabolic process in the plants (Usano-Alemany *et al.,* 2014). The nuts from Gerei, Adamawa state, showed no significant fiber content when compared with nuts from other states which showed some levels of fiber with those from Nsukka, Ochaja and the yellow variety cashew nuts from Okigwe been relatively low (at 1.94%, 1.38% and 187% respectively) as against 2.80%, 2.29% and 6.44% recorded for cashew nuts from Umuahia, red variety cashew nut from Okigwe and the cashew nuts from Isiukwuato. Cashew nuts known to be rich in oil (Akinhanmi, 2008) but the crude fat content of cashew nuts sourced from Nsukka, Enugu State recorded a low percentage at 7.14% when compared to those from other location considered in the review. This difference may be due to seasonal changes, harvest and food processing operation employed during the sample preparation or some storage factors. Some of these factors are likely to be the cause of the low ash content recorded for cashew nut sourced from Ocahaja, kogi State and also the subsequent cause of the high carbohydrate content recorded for sample sourced from Nsukka and Gerei both in Enugu and Adamawa States respectively at 52.3% and 45.78% when compared with the ones sourced from other locations (Fig. 1).

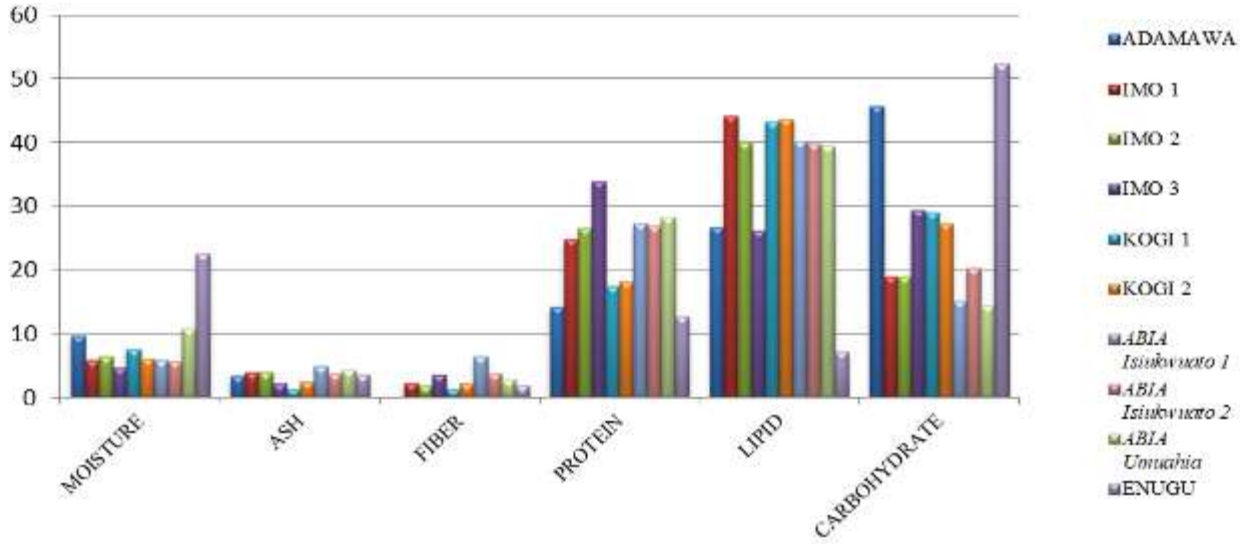

Figure 1. Comparison of the Proximate Compositions of Cashew Nuts sourced from Gerei in Adamawa State, Okigwe in Imo State, Ochaja in Kogi State, Isiukwuato in Abia State, Umuahia in Abia State and Nsukka in Enugu State

Cashew nuts from Isiukwuato, Okigwe and Nsukka were reviewed for the comparison of selected phytochemical constituents which are: phytate, tannin and alkaloid. Nuts (yellow variety of cashew nut) from Okigwe was recorded to have low tannin content (0.1849mg) compared to those from Isiukwuato and Nsukka with 1.75mg, 1.66mg and 0.765mg respectively) but the alkaloid content of the ones sourced from Enugu State is significantly lower (Fig. 2). These significant differences might

ISSN: 2814-0508

be as a result of the weather situation of the area of cultivation which might subsequently affect the metabolism of these secondary metabolites and can also be as a result of the post-harvest methods employed in the processing of the nuts or as a result of some seasonal or environmental differences. These conditions might subsequently be responsible for the differences and non-uniformity in the selected mineral contents (potassium, magnesium, phosphorus, zinc and iron) of nuts sourced from Nsukka and Okigwe (Fig. 3).

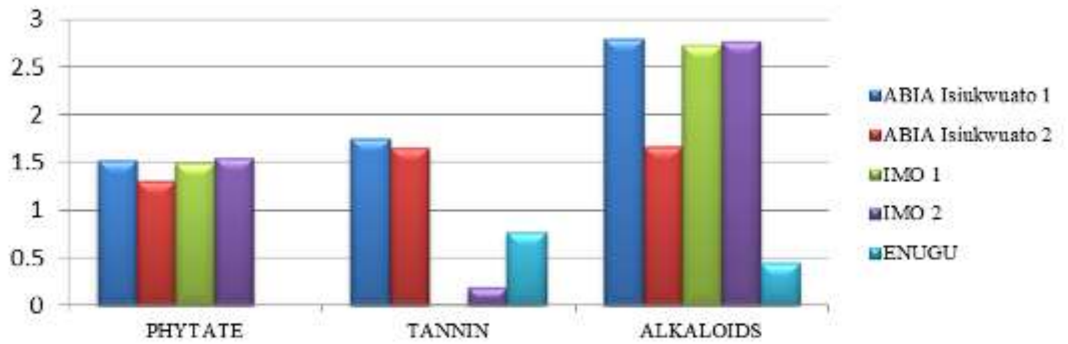

Figure 2. Comparison of the Phytochemical Compositions of Cashew Nuts sourced from Gerei in Adamawa State, Okigwe in Imo State, Ochaja in Kogi State, Isiukwuato in Abia State, Umuahia in Abia State and Nsukka in Enugu State

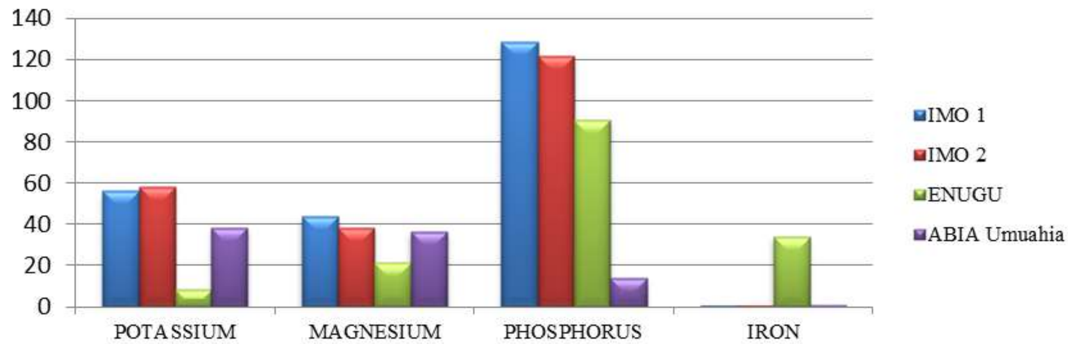

Figure 3. Comparison of Some Selected Mineral Compositions of Cashew Nuts sourced from Gerei in Adamawa State, Okigwe in Imo State, Ochaja in Kogi State, Isiukwuato in Abia State, Umuahia in Abia State and Nsukka in Enugu State

CONCLUSION

This desk review of journals showed that cashew nuts from different location have the tendencies of having different nutritional and medicinal values in terms of their proximate, phytochemical and mineral contents despite the fact that it has been said to able to grow well in tropical climatic conditions (Akinhanmi, 2008). Some of these differences can be based on the post-harvest operations used in their processing and others based on the seasonal or weather and environmental conditions of their plantation locations. There is therefore need for cashew farmers and stakeholders in cashew nut processing in Nigeria to take precautions before, during and after cultivation of cashew plants so as to maintain the quality (most especially chemical properties) of the plant as this remain major reason for its economic importance.

ABSTRACT

A study was carried out at the Department of Value Addition Cocoa Research Institute of Nigeria, Ibadan, Oyo State, Nigeria to investigate the effect of different processing methods on the Proximate, Mineral and phytochemical screening of Cashew Apple Waste (CAW). Matured and ripe cashew fruits are harvested from cashew plantations of the cocoa research institute of Nigeria, the nuts were detached and the cashew apple was divided into three samples (A, B and C) and were processed using different methods which were blanched, unblanched and fermented. The CAW was then sundried for 5-7 days for proper drying. All the processed CAW were then milled into a fine powder to pass through a 2mm mesh sieve and samples were collected, labelled and were taken to the laboratory for various analysis such as proximate composition, mineral analysis, phytochemical screening and anti-nutritional factors. Result on the proximate composition showed that blanched CAW was significantly ($P<0.05$) higher in all the parameters assayed except for moisture content which was similar. Mineral element composition showed that Ca^{2+}, Fe^{2+}, Mg^{2+}, K^{+} and $PO4^{-}$ were significantly ($P<0.05$) highest in blanched CAW. Phytochemical screening also revealed that flavonoids, alkaloids, tannins, phenolics, saponins, phytates, oxalates and steroids values were higher significantly ($P<0.05$) in blanched CAW. It was therefore concluded that cashew apple waste will exhibit its highest photobiotic potentials and nutrient qualities if it is processed through blanching and the juice mechanically extracted.

Key words: Cashew Apple Waste, Proximate analysis, Mineral composition, Phytochemical screening

INTRODUCTION

The *Anacardiaceae* family has 76 genera divided into five tribes (*Anacardiaceae, Dobineae, Rhoeae, Semecarpeae* and *Spondiadeae*) covering about 600 species (Correia *et al.,* 2006). *Anacardium occidentale* is an abundant tree in the Middle Belt of Nigeria. This species is unique for its antioxidant (Melo-Cavalcante *et al.,* 2003), antigenotoxic, antimutagenic (Melo-Cavalcante *et al.,* 2011), antiulcerogenic (Behravan *et al.,* 2012), anti-inflammatory (Olajide *et al.,* 2004), antibacterial, antifungal and larvicides (Behravan *et al.,* 2012) properties. Also, it is rich in anthocyanins, carotenoids, ascorbic acid (vitamin C), flavonoids and other polyphenols as well as mineral components. After the extraction of the juice, most times we are left with the Cashew Apple Waste (CAW) that is usually discarded. It is a waste obtained after the juice has been extracted from the apple of the cashew fruit after the detachment of the cashew nut. Cocoa Research Institute of Nigeria (CRIN) produces several hectrages of cashew as one of their mandate crops and have been extracting and processing the fruit juice but the CAW, which could be further processed into feed ingredient for livestocks, has always been discarded over the years. There is dearth of information on its utilization as livestock feed but research is recently geared toward assessing its chemical composition to ascertain its phytochemical potentials and then put it to right use. Dos santos Lima *et al.,* (2012) reported that the cashew (pulp) biomass has great potential for bioprocess after pre-hydrolysis and it is a promising raw material for bioethanol production, with 12% of hexoses, and 88% pentoses. CAW could also serve as a good source of sugars for ethanol production. This study is focused on assessing the phytobiotic potentials of cashew apple waste as livestock feed by evaluating its proximate composition, mineral contents and antinutritional factors.

MATERIALS AND METHODS

Location of the study

The investigation was carried out at the Department of Value Addition Cocoa Research Institute of Nigeria, Ibadan, Oyo State, Nigeria.

Sourcing and Processing of Raw materials

Matured and ripe cashew fruits are harvested from cashew plantation of the cocoa research institute of Nigeria, Ibadan in a basket to the production centre. The bad and damage cashew apple were sorted from the good ones, washed with clean water, the nuts detached from the apple. The cashew apple was divided into three samples (A, B and C) and were processed using different methods as stated below.

Sample A: Unblanched Cashew Apple Waste

The properly washed cashew apples were juiced mechanically using a manual mechanical juice extractor fabricated by Cocoa Research Institute of Nigeria (CRIN). The waste were collected and sundried for 5-7 days for proper drying.

Sample B: Blanched Cashew Apple Waste

The cashew apples were placed in a cooking pot with hot water for 10 minutes with intermittent stirring of the apple after which a manual mechanical juice extractor was used to extract the juice and the waste were collected and sundried for 5-7 days for proper drying.

Sample C: Fermented Cashew Apple Waste

The cashew apples were also juiced with the mechanical extractor and the waste were packed in air-tight polythene bag and fermented for 7 days and then were sundried for 5-7 days for proper drying. All the processed CAW were then milled into a fine powder to pass through a 2mm mesh sieve and samples were collected and were well labelled and were taken to the laboratory for the various analysis.

Proximate analysis

The moisture content, ash, crude fibre and crude fat, were determined using the method described by AOAC (1990). The crude protein was also determined by Kjeldahl method. The energy value was determined using an Adiabatic Oxygen Bomb calorimeter (12149 Adiabatic Calorimeter, PARR instrument Co. Illinois USA.

Mineral Analysis

The mineral content of the samples was analyzed by using atomic Absorption spectrophotometer (AAS) for the following metals: Ca, K, Fe, Zn, Mg, PO_4^- and Mn while the Flame Photometer was used in the analyses of K (Ahmed, 2015).

Phytochemical Screening

The samples of cashew apple waste were tested for specific presence of certain phytochemicals according to the method of (Harbone, 1998; Tiwari *et al.,* 2011). Alkaloids were determined using the Wagner's test. Two ml of each of the samples were treated with few drops of Wagner's reagent (iodine-potassium iodide solution). Flavonoids were determined using Alkaline reagent test where two ml of the extracts was treated with few drops of 2mL NaOH. Tannins were obtained with Gelatin test (two ml of the extracts was treated with few drops of 1% gelatin solution containing NaCl). Phenols were determined using the Ferric chloride test while, Triterpenes was determined using the Salkowski's test. Two ml of the extracts was treated with few drops of chloroform and then filtered. The resulting solutions was then treated with few drops of concentrated H_2SO_4, shaken, and allowed to stand for 5 minutes.

Saponins were obtained using the Froth test while glycosides were analysed using the Legal's test where two ml of the samples were treated with few drops of Sodium nitroprusside in pyridine and NaOH. Cyanogenic glycosides (Picrate paper test): Two ml of the extracts was treated with few drops of 10mL water and 1mL dilute HCl. Picrate papers (paper strips dipped in saturated aqueous picric acid previously neutralized with NaHCO3) and suspended above flask containing the solution. The solution was warmed at 45^{o}C for an hour. Phytases (Liebermann-Burchard's test): Two ml of the extracts was treated with few drops of chloroform and then filtered. The resulting solutions were treated with few drops acetic anhydride, boiled and then cooled. Concentrated H_2SO_4 was added after cooling. Amino acids (Ninhydrin test): Two ml of the extracts were treated with few drops of 0.25% w/v ninhydrin and then be boiled for 5 minutes. Vitamins such as acsorbic acid, beta-carotene, thiamin, riboflavin, niacin, were also analysed

Statistical Analysis

The data obtained was subjected to analysis of variance (ANOVA) using Statistical Products for Service Solutions (SPSS) version 21.0. The data obtained were presented as means and standard deviation of the samples. Significant means were separated using the Duncan Multiple Range Test (DMRT) at P≤0.05.

RESULTS

Proximate composition of differently processed CAW

The result of the proximate composition of differently processed cashew apple waste as presented in Table 1. There was no significant (P>0.05) variation in the values of moisture content of the cashew apple waste on the three processing methods used. Crude protein content was however significantly (P<0.05) highest (19.50%) in blanched CAW and lowest (9.75%) in those fermented. Crude fat content was significantly (P<0.05) highest

(2.13%) in blanched CAW and lowest (0.35%) in those that were unblanched. Crude fibre showed significantly (P<0.05) higher mean value of 27.70% in unblanched CAW and lowest (15.17%) in those cashew that were blanched. Crude Ash content was significantly (P<0.05) highest (11.77%) in blanched CAW and lowest (9.90%) in those fermented. NFE content was also higher significantly (P<0.05) in blanched CAW with an average value of 49.07% and lowest (40.67%) in fermented cashew apple waste.

Table 1: Proximate Composition of Cashew Apple waste extracted using different methods

Parameters	Unblanched CAW	Blanched CAW	Fermented CAW	SEM±
Moisture (%)	8.33	8.80	8.33	0.23
Crude protein (%)	12.03[b]	19.50[a]	9.57[c]	1.07
Crude Fat (%)	0.37[c]	2.13[a]	1.47[b]	0.14
Crude Fibre (%)	27.70[a]	15.17[c]	21.57[b]	6.28
Crude Ash (%)	10.53[bc]	11.77[a]	9.90[c]	2.75
NFE (%)	40.67[c]	42.63[b]	49.07[a]	8.76

CAW = Cashew Apple Waste, SEM = Standard Error of Means. Means with same letters are not significantly different (P≤ 0.05) across the rows

Mineral composition of differently processed CAW

The result of the mineral composition of differently processed cashew apple waste as presented in Table 2. Calcium content was significantly (P<0.05) highest (265.00mg/100g) in blanched CAW and lowest (153.33mg/100g) in those samples from unblanched cashew apple waste. Iron content followed the same trend with highest mean value of 10.20mg/100g in blanched CAW and lowest in those samples from unblanched cashew apple waste with an average value of 7.33mg/100g. Zinc content on the other hand was similar (P>0.05) among the various samples. Magnesium content showed significantly (P<0.05) variation with highest (110.00mg/100g) in blanched CAW and least value (70.00mg/100g) in those samples from unblanched CAW. Manganese content showed no significant (P>0.05) variation among the three samples but however the value was higher (0.35mg/100g) in those samples that was fermented. Potassium content was significantly (P<0.05) highest (80.00mg/100g) in blanched CAW and lowest (51.67mg/100g) in those samples from unblanched CAW. Phosphate content was significantly (P<0.05) highest (151.67mg/100g) in blanched CAW and lowest (120.00mg/100g) in those samples from unblanched CAW.

Table 2: Mineral Composition of Cashew Apple waste extracted using different methods

Parameters	Unblanched CAW	Blanched CAW	Fermented CAW	SEM±
Calcium (mg/100g)	153.33[c]	265.00[a]	178.33[b]	24.06
Iron (mg/100g)	7.33[b]	10.20[a]	8.97[c]	3.27
Zinc (mg/100g)	0.30[c]	0.53[a]	1.10[b]	0.06
Magnessium (mg/100g)	70.00[a]	110.00[c]	83.33[b]	23.46
Manganese (mg/100g)	0.02	0.03	0.35	0.03
Potassium (mg/100g)	120.00[bc]	51.67[a]	35.00[c]	22.26
Phosphate (mg/100g)	51.67[c]	80.00[b]	65.00[a]	8.24

CAW = Cashew Apple Waste, SEM = Standard Error of Means. Means with same letters are not significantly different (P≤ 0.05) across the rows

Phytochemical screening of differently processed CAW

The result of the phytochemical screenings of differently processed cashew apple waste as presented in Table 2. Flavonoid content was significantly (P<0.05) highest (388.33mg/100g) in blanched CAW and lowest (140.00mg/100g) in those samples from unblanched CAW. Alkaloids content was also significantly (P<0.05) highest (861.67mg/100g) in blanched CAW and lowest (551.67mg/100g) in those samples from fermented CAW. Tannins values showed significantly (P<0.05) variations with highest mean value (480.00mg/100g) in blanched CAW and least mean value (433.33mg/100g) in fermented CAW. Phenolic, terpinoid and saponins content were significantly (P<0.05) highest (49.00, 520.00 and 240.00mg/100g) in blanched CAW while lowest (30.50, 220.00 and 166.67mg/100g) in those samples from unblanched CAW. Cardiac glycosides and cyanogenic glucosides values showed no significant (P>0.05) variation among the three samples. Phytates and Oxalates content were significantly (P<0.05) highest (75.00 and 20.00mg/100g) in blanched CAW while lowest (6.66 and 65.66mg/100g) in those samples from unblanched CAW. Steroids and Antioxidant inhibitors values were also significantly (P<0.05) highest (94.67and 42.37mg/100g) in blanched CAW while lowest (65.66 and 23.33mg/100g) in those samples from unblanched CAW.

Table 3: Phytochemical screening of Cashew Apple waste extracted using different methods

Parameters	Unblanched CAW	Blanched CAW	Fermented CAW	SEM±
Flavonoid (mg/100g)	140.00^{c}	388.33^{a}	238.33^{b}	32.64

DISCUSSIONS

Proximate composition

Moisture content is one of the most important and widely used measurements in the

ISSN: 2814-0508

processing, preservation and storage of foods and drugs (Oloyede, 2005). The similarity in the moisture content of the three processed samples is a pointer to the fact that they will have longer shelf life and high storability due to its insusceptibility to microbial attacks. This justifies the practice of storage in dry form by users. Chirife and Fontana, (2008) reported that low water activity can inhibit the proliferation of microorganisms and enzyme activity, leading to increase storability of samples. The higher ash content recorded for blanched CAW showed higher mineral content than those on other samples as ash content of any organic material is a reflection of the mineral content of the material. This finding is supported by the report of (Okpanachi et al., 2016) who observed a high ash content in dry cashew pulp during a laboratory analysis for proximate composition. Many body functions depend on lipids. Lipids provide excellent source of energy and enhance transport of fat-soluble vitamins, insulate and protect internal tissues and contribute to vital cell processes (Pamela *et al.,* 2005). The higher fat content recorded in blanched CAW is a pointer to the fact that this product has the potential to supply livestocks with needed energy. The low crude fibre content observed for blanched CAW is advantageous to the absorption of glucose and fat. Although crude fibre enhances digestibility, its presence in high levels can cause intestinal irritation, lower digestibility and decreased nutrient utilization. Crude fibre in foods or plants is an indication of the presence of non-digestible carbohydrate and lignin. The low value obtained for blanched CAW is considered appropriate and studies have shown that crude fibre aids in reducing peaks of blood glucose following a meal due to delayed gastric emptying (Jones, 1995). The highest protein value recorded among blanched CAW could be as a result of the blanching process that reduces the anti-nutrients and make the protein available. The protein from plant sources have lower quantity, but their combination with many other sources of protein such as animal protein may result in equivalent nutritional value. The higher NFE in fermented CAW could be as a result of the fermentation process as its known to break down higher organic matter to release carbohydrate (Trease and Evans, 2001).

Mineral composition

Calcium content was found to be higher among blanched CAW compared to other samples such as unblanched and fermented CAW. Calcium is necessary for the strong bones and teeth. It is relatively high in cereals, nuts and vegetables (James, 1996; Thomas, 2006). Iron content was also found to be higher among blanched CAW compared to other samples such as unblanched and fermented CAW. It is essential for transport of oxygen in hemoglobin and also involves in energy metabolism. Deficiency of iron results in anaemia. This result obtained shows that it can be used in improving the anaemic condition in iron deficient animals as reported by (Bolt, 1998, Takeri, 2004). Potassium was higher in blanched CAW compare to others samples. Potassium is responsible for nerve action and is very important in the regulation of water and electrolyte balance and acid – base balance in the body. The high level of potassium in blanched CAW is a good indication that its consumption will enhance the maintenance of the osmotic pressure and acid-base equilibrium of the body. Magnesium is essential for enzyme reaction in the metabolism of ingested carbohydrate, example of such enzymes are α-amylases, maltase, sucrase and lactase. It is essential in electrical breakdown of nutrient and other materials within the cells (Bolt, 2008). From this present study, blanched CAW showed higher magnesium content. Manganese is also an essential mineral as it helps the body form connective tissues bones, blood clotting factors and sex hormones. It also plays a role in fat and carbohydrate metabolism, calcium absorption and blood sugar regulation. It helps also to regulate normal brain and nerve function. The study however shows similarity among the manganese content of the various samles. Phosphate was found to be higher among the cashew apple that was blanched and mechanically extracted. This element found more in this treatment is a constituent of bone and teeth, nucleoprotein, phospholipids, enzymes and high energy compounds. (Jones, 1995). Zinc is essential in the activation of certain enzymes, these include dehydrogenase, alkaline phosphatase and carboxypeptidase. Zinc containing organic compounds employed as astringent and anti- fungal agents. Zinc aids wound healing and metabolism of nucleic acid and insulin (Takeri, 2004). It is however found to be higher among the cashew apple that were blanched compared to other samples.

Phytochemical screening

Flavonoids has been shown to possess many pharmacological properties such as: anti-oxidant activities, anti-inflammatory activities, anti-cancer activities and anti- microbial effects, hence, flavonoids may have a contributory effect to its fertility properties and other pharmacological effects the plant possesses (Wu et al., 2003, Verma et al., 2011). Hence the higher flavonoids present in the blanched CAW is of immense advantage to livestocks. The antioxidant activity of flavonoids is efficient in trapping superoxide anion (O_2), hydroxyl (OH), peroxyl (ROO) and alcohoxyl (RO) radicals. Alkaloids are generally toxic to other organisms. They often have pharmacological effects and are used as medications, as antimicrobial, antipyretic, local anesthetic and stimulant, psychedelic, analgesic, antibacterial, anticancer, antihypertension agent, the cholinomimetic, anticholinergic, vasodilator antiarrhythmic, antiasthma and antimalarial. Hence, the presence of alkaloids in the blanched CAW confirms its uses as a potential material in livestock feed. The presence of Tannin in the samples with higher value among blanched CAW comparable to other shows antitumor, hepatoprotective and antioxidant potentials. Alkaloids and tannins may also contribute to the plant's effects as antimalarial, anti-diarrhoea and analgesic agents (Mir, 2013). Phenolic compounds are secondary metabolites in plants that are involved in a number of metabolic pathways and are essential for plant growth and reproduction, and as protecting agents against pathogens. Phenolic compounds may play an important role in preventing chronic illnesses such as cardiovascular disease, certain type of cancers, neurodegenerative disease, and diabetes. Blanched cashew apple gave higher phenolic compound which proves the plant to be a viable phytobiotics which could replace the use of antibiotics in poultry production (Asl Marjan and Hossein, 2008). Blanched cashew apple shows higher saponin content comparable to other samples. Saponins are being used commercially as dietary supplements and nutraceuticals. Saponins are expected to lead to hydrolysis of glycoside from terpenoid and hence reduce the toxicity associated with the intact molecules. (Asl Marjan and Hossein, 2008). Anti-nutrients such as cardiac glycosides and cyanogenic glucosides, phytates, oxalates present in this plant is in low amount such that they do not pose much serious health threat to consumers. Since the levels of these Anti nutrients are not above the lethal dosage approved by standard bodies like National Agency for Food and Drugs Administration and Control (NAFDAC) in Nigeria, consumption of the material by livestocks may be considered to be non-toxic and may not elicit any adverse effect on the nutritional values of the by product (Blessing *et al.,* 2011). Higher level of phytate above that reported in this study for blanched cashew apple waste have been reported to have complicated effects in human and livestock system including indigestion of food and flatulence (Maynard *et al.,* 2004). They have also been known to exert substantial effect on bioavailability of minerals in foods by forming complexes with minerals (such as Ca, Zn and Mg), thereby preventing efficient absorption by the body systems (Oboh *et al.,* 2003). However, extensive and proper processing methods such as blanching is needed to reduce some of these anti-nutrients. Higher oxalate and tanin concentration above that reported in this study in blanched CAW could cause great risk of renal absorption and also possess the ability to chelate divalent minerals and prevent their absorption by the body systems However, the levels of oxalate was reduced to this bearable level because the sample was subjected to heat treatment (Blanching) (Lumu *et al.,* 2011). Steroids are known or have been found as an anti-inflammatory agent, anti-tumor, immunosuppressants and, hepatoprotective, antibacterial, plant growth hormone regulator, anthelminthic, cytotoxic and cardiotonic activity. Been higher in blanched CAW shows that the plant has promising phytobiotic potentials in livestock feeding.

CONCLUSION

Choices of processing method of cashew apple play important roles on the quality of the by product (Cashew apple waste) and bioactivity of the product. Based on the above findings it was concluded therefore that cashew apple waste will exhibit its highest phytobiotic potentials and nutrient qualities if it is processed through blanching and the juice mechanically extracted.

ABSTRACT

African seasonings are commonly used to enhance the taste of locally made dishes. These various seasonings are gotten from plant sources and could be in form of seeds, roots, bark, or flowers. Fermented food flavoring condiments are usually derived from the fermentative activities of microorganisms on vegetable proteins of legumes or oil seeds, which abound in Nigeria. These condiments, apart from their flavoring properties, also serve as an affordable and ready source of plant protein to the Nigerian populace, whose staple foods are mainly carbohydrate based. This work, therefore aimed at comparing the nutritional values of two local condiments in their raw and processed forms: Parkia biglobosa (parkia seeds, Iru woro, and iru pete) and Citrullus colocynthis (egusi and ogiri). Proximate analyses were carried out on samples of both condiments. Results showed that processed melon seeds (ogiri) had the highest values for protein and moisture content (20.12% and 70.37% respectively) and the lowest values for ash content, fat, crude fibre and carbohydrate (1.01%, 2.12%, 1.92%, and 4.47% respectively), while the unprocessed melon seeds (egusi), had the highest fat content among all the samples. Processed pete had the highest values of ash, fat, fibre, and carbohydrate content when compared with ogiri and Iru woro. Unprocessed P. biglobosa seeds had higher protein, ash, crude fibre, and carbohydrate values (17.47%, 7.91%, 8.72%, and 43.6% respectively), when compared with unprocessed C. colocynthis seeds which had higher moisture and fat contents (43.1%, and 30.51% respectively).

Key words: *Parkia biglobosa,* African parkia seeds, melon seeds, ogiri, iru, fermentation, proximate analysis

INTRODUCTION

African food preparation is not complete without the use of locally available seasonings. Just as salt is important in meal preparation, the addition or omission of some locally made seasonings can make or break a dish. The various seasonings are gotten from plant sources and could be in form of seeds, roots, bark, or flowers. These items follow various preparation procedures from drying and grinding to soaking and leaving whole. Fermented foods constitute a significant component of African diets (Olasupo and Okorie, 2019). Apart from increasing the shelf life and reduction in the anti-nutritional factors, fermentation markedly improves the digestibility, nutritive value and flavours of the raw seeds (Dosunmu et al., 2012). A condiment is defined as a spice, sauce, or other food preparation that is added to food to impart a particular flavor or enhance its taste (example salt). These fermented food condiments are known to be good sources of proteins and vitamins. Indeed, seasonings are an essential key to cooking in Nigeria as no cooking is complete without the addition of one form of seasoning or the other. Seasonings include local and imported brands. Local seasonings can be used singly to cook a special variety of soups. For instance, among the Igbos, *ogiri* is used to cook bitter leaf soup while *iru* or *dawadawa* is used in cooking egusi soup. In addition to the aforementioned benefits of such condiments, they are also employed in dietary strategies to control obesity due to their high fibre, low carbohydrate and fat contents rather than physical exercises (Dosunmu et al., 2012).

Parkia biglobosa

Parkia is a pantropical genus of about 30- 40 tree legume species of considerable evolutionary, taxonomic, biological and economic importance in Africa, Asia and South America. It has several uses including fodder, food, medicine, green manure, fuel and timber (Sabiiti and Cobbina, 1992). The products vary by ethnic groups according to tastes and availability. Citing a number of studies in Togo, Ghana and Nigeria, Campbell-Platt (1993) reported a daily consumption of fermented *Parkia biglobosa* seeds of 1-17g per person in West Africa in central Benin; women reported using between 33g and 66g of locust bean per household per day or 7g – 10g per person. *Iru* is one of the natural sources of plant proteins which gives it a great potential as protein supplement. It is used in the preparation of various delicacies, such as vegetable soups and stews and also a low cost meat substitute that contributes to protein and calories intake by several West African families (Ogunshe and Okereh, 2011).

Figure 1. (a) Unfermented seeds of African locust bean (b) Fermented seeds of African locust bean (Iru) (c) Unfermented melon seeds and (d) fermented melon seeds (Ogiri). Source: Olasupo and Okorie, 2019.

Citrullus colocynthis

Melons are widely grown and consumed in Nigeria. Melon crops provide a source of income to many Nigerians. Melon planting occurs mostly in the Northern portion of the country because the amount of rainfall aids melon growth. For Nigerians, melons are an important source of vitamins such as vitamin A and vitamin C and the seeds are high in protein. Melons are major food crops with several varieties which serves as major food sources (Jacob et al. 2015). The melon crop is scientifically known as *Citrullus colocynthis* and locally known as egusi. Egusi is grown not for its flesh but for its seeds. Only the seeds are edible as the fruit is too bitter. The seeds are eaten in various forms.

Research has proven that the bioactive compounds found in egusi have a protective effect against coronary heart disease and promote the absorption of fat-soluble vitamins as they exhibit antioxidant, antiviral, antidiabetic, hepato protective and cardio protective properties (Acham et al. 2018).

Ogiri is a seasoning native to Nigeria, West Africa. It is a paste of fermented oil seeds. There are many types of Ogiri but the most common varieties are Ijebu, Igbo and Nwan. Its seeds are from West African melons, whose fruit is bitter and inedible. The seeds are covered with a light brown shell which is removed prior to cooking. When de- shelled, the seeds have a creamy white appearance and it is ground into powder that has a consistency of bread crumbs. They are then used to cook very savory stews and served with the staple fufu or pounded yam. Ogiri has an oily grey pasty consistency and a very strong pungent smell. The smell is greatly reduced when frozen. Ogiri is best used in the preparation of egusi soups. It lends a deeper, richer flavor to the dish. This work was aimed at assessing the nutritional values of two locally made condiments in Nigeria; *Parkia biglobosa* & *Citrullus colocynthis* (unprocessed and processed).

MATERIALS AND METHODS

The two condiments used and their seeds were obtained from the market. Iru, ogiri and *colocynth* seeds were obtained from Dugbe market while *Parkia* seeds were obtained from Bodija market. The proximate analysis was carried out at IAR&T central laboratory, Apata, Ibadan, Oyo state.

Proximate Analysis

Proximate analyses were carried out using FAO recommended methods for proximate composition: oven drying for moisture content, Kjeldahl method with 6.25 conversion factor for crude protein, Soxhlet solvent extraction for crude fat, dry ashing for ash and (total or available) carbohydrates by difference.

RESULTS AND DISCUSSION

ISSN: 2814-0508

Processed *woro*	12.76	17.1	7.61	2.14	7.25	51.35
Processed *pete*	19	14.69	7.69	2.61	9.79	43.64
Ogiri	20.12	70.37	1.01	2.12	1.92	4.47
Egusi	12.16	43.61	3.07	30.51	4.06	6.06

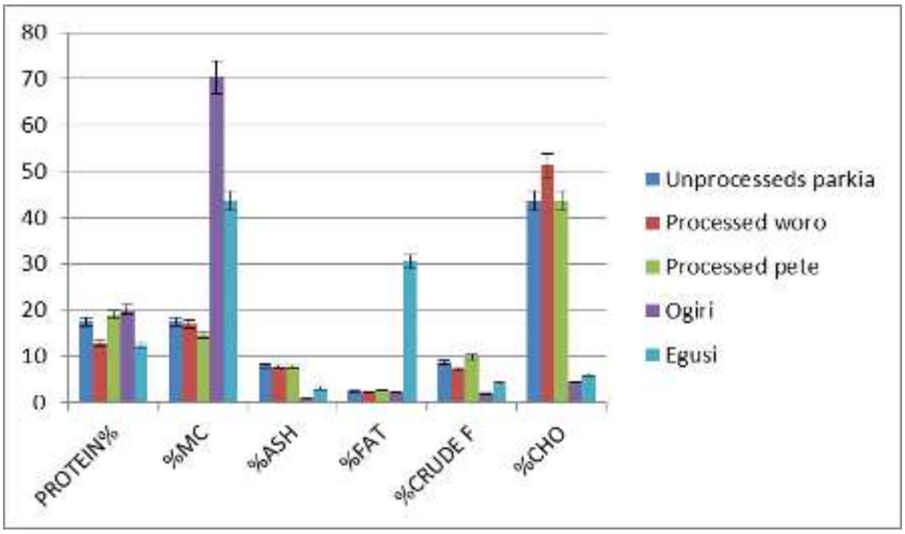

Figure 2. Comparison chart of proximate results of Parkia and melon samples

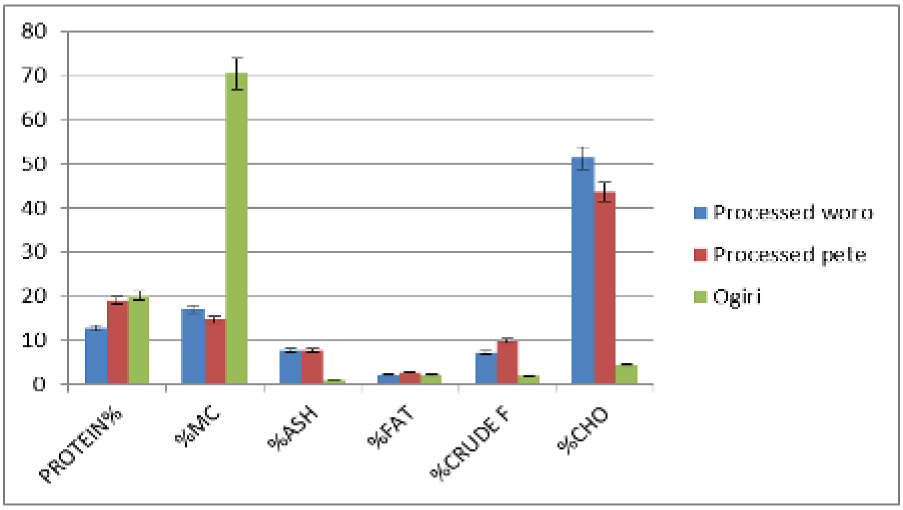

Figure 3. Comparison chart of proximate results of *Iru woro*, *Iru pete*, and *ogiri* samples

From the table and figures above, it was shown that processed melon seeds (ogiri) had the highest values for protein and moisture content (20.12% and 70.37% respectively) and the lowest values for ash content, fat, crude fibre and carbohydrate (1.01%, 2.12%, 1.92%, and 4.47% respectively), while the unprocessed melon seeds (egusi), had the highest fat content among all the samples. Processed *pete* had the highest values of ash, fat, fibre, and carbohydrate content when compared with *ogiri* and *Iru woro.* Unprocessed *P. biglobosa* seeds had higher protein, ash, crude fibre, and carbohydrate values (17.47%, 7.91%, 8.72%, and 43.6% respectively), when compared with unprocessed *C. colocynthis* seeds which had higher

ISSN: 2814-0508

moisture and fat contents (43.1%, and 30.51%, respectively).

CONCLUSION AND RECOMMENDATIONS

Parkia biglobosa seeds (both unprocessed and processed) and *Citrullus colocynthis* seeds are very nutritious with processed *pete* being more nutritious than processed *woro* seeds, while *ogiri* had high protein content. It is, therefore, recommended that processed (fermented) *Parkia biglobosa* seeds (*pete*) should be consumed more as it is the most nutritious product of the *Parkia* tree. Processing it into powder is also suggested.

ABSTRACT

Chrysophyllum albidum is an important but highly underutilized tree crop in Nigeria's food systems. Two varieties, yellow fleshed fruit and red fleshed fruits were considered in this study. Fresh fruits were randomly collected from Eastern parts of the country, and washed to remove dirts. The pulp and the peel were separated and the pulp was stored for analysis. The phytochemical and proximate compositions were determined using standard analytical methods. Phytochemical and antioxidant activity such as total phenol, total flavonoids, total antioxidants, DPPH were significantly higher in yellow fleshed fruit than in red fleshed fruit. Carbohydrate, fat composition, pH value and Brix were higher in red fleshed fruit than in yellow fleshed fruit. This study shows that the yellow fleshed C. albidum, which is less consumed than the red fleshed fruits. are very good source of natural antioxidant and can contribute towards food and nutritional security in Nigeria.

Key words: *Chrysophyllum albidum*, phytochemicals, pulp, nutritional security

INTRODUCTION

Chrysophyllum albidum (African star apple) belongs to the family *Sapotaceae* which is made up of 17 genera and 7 commonly found species (Bada, 1997). The name *Albidum* originated from the white or silvery –grey undersurface of its mature leaves. It is termed star apple because of the star-like arrangement of its seeds as found in an apple (Adu-Baoudu, 2009). It is a tree crop commonly found in the rainforest or the riverine areas of the savanna/rainforest zone. Its distribution spans Central, Eastern and Western Africa (Nigeria, Ghana, Republic of Benin, Uganda, Niger, Cameroun, and Cote d' Ivoire) (Adebayo *et al*., 2011). *C. albidum* is a common tree/shrub in home gardens of Southern Nigeria being a seasonal fruit tree which produces flowers at the end of the rainy season (Oct/Nov) and fruits in the peak of dry season (December to April). However, in parts of the rainforest of South Eastern states of Nigeria, flowering occurs January-February; April-June and September with the variation in its flowering regime making it a good tool for apiculture (Okafor, 1981). Among all the species of *Chrysophyllum* found in Nigeria, C*hrysophyllum albidum* remains a commonly consumed and utilized variety. It is grown for its nutritional and economic value. However, it has been tagged as an endangered, neglected and underutilized fruit tree (Eguagie, 1997). It has been tagged as one of the trees of life and among the top 5 priority indigenous tree crops because of the role it plays in the food systems and economy of rural people in West Africa's humid lowlands (Leakey, 2012). The top priority indigenous tree crops highlighted by Leakey (2012) are *Irvingia gabonensis* (Bush Mango), *Dacryodesedulis* (African Plum or African Pear), *Ricinodendrum heudolotti* (Njangsang in cameron), *Garcinia kola* (Bitter kola) *and Chrysophyllum albidum* (African star Apple). *C. albidum* can be used for wine production, jam, gum making, animal feed production (Makinde *et al.,* 2017). This study therefore aims at evaluating the phytochemical, proximate and antioxidant composition of 2 varieties found in Nigeria.

MATERIALS AND METHODS

Fresh fruits of the red and yellow fleshed varieties were randomly collected from the Eastern states and washed to remove presupposed dirts. Composite sample of each variety was prepared by scraping the pulp of the fruit and separating from its seed with spatula. The pulp was blended thoroughly using a waring blender (model of blender) and divided into two portions. One portion was used for fresh analyses (moisture content, vitamin C, titratable acidity, brix determination), while the other portion was oven dried at 55 °C for 48 h and used for other determinations.

The %pH, Brix and total titrable acidity were measured by standard methods while the total phenolic, flavonoids, total antioxidants and reducing capacity (using Ferric Reducing Antioxidant Power-FRAP and 1,1-diphenyl-2-picryl hydrazyl-DPPH radical scavenging) were determined spectrophotometrically using standard procedures. Proximate analysis was carried out on the samples to determiune the moisture, crude fiber, protein, ash, carbohydrate and crude fat contents. The moisture, crude fiber and ash contents of the

ISSN: 2814-0508

samples were determined by the method described by Pearson, (1976). The micro-kjedahl method was used to determine crude protein using the methods of AOAC (2000). The protein was calculated using the general factor 6.25 to convert the Nitrogen to protein(AOAC,2000). The percentage total carbohydrate was estimated as the difference between 100 and the sum total of the proximate composition of each sample (Nzikou et al.,2010).

All analyses were carried out in triplicates and data were expressed as means ± standard deviation. Analysis of Variance (ANOVA) was performed to calculate significant difference in treatment means. Fisher test was used in determining the least significant difference(LSD) of the mean. Test of significant was done at 5% probability level (P=0.05).

RESULTS

Phytochemical and proximate compositions of the red and yellow fleshed pulp of *C. albidum* are presented in the tables 1and 2 below, respectively. At p≤0.05, YFP had significantly higher values of total phenolic (1.71 ± 0.06 mg/g), total flavonoid (2.01 ± 0.02 mg/g), total antioxidant (1.04 ± 0.02 mg/g), Vitamin C (0.29 ± 0.11 mg/g), Protein (4.31 ± 0.02 %), Moisture (68.47 ± 0.23 %), crude fibre (1.66 ± 0.01 %) and TTA (1.29 ± 0.08 mg/g) compared to those of RFP while significantly higher values were recorded for RFP for Reducing power (2.10 ± 0.06 mg/g), fat (0.27 ± 0.00 %) and CHO (33.66 ± 1.34 %) when compared with values for YFP. RFP was found to be significantly less acidic (3.80 ± 0.03) than YFP (3.67 ± 0.04). Brix was higher in RFP than in YFP (16.33 ± 0.58^0 and 10.67 ± 1.15^0, respectively) which showed that the YFP is less sweet than the RFP and its corroborated by the low pH value recorded by the YFP. Significantly high values of DPPH inhibition were observed in the YFP (52.03%) compared to the RFP.

Table 1: Phytochemical compositions of yellow- and reddish-fleshed pulp of *C. albidum*

Parameter	Yellow	Red
Total phenolic (mg/g)	1.71 ± 0.06^a	1.58 ± 0.02^b
Flavonoids (mg/g)	2.01 ± 0.02^a	0.85 ± 0.04^b
Reducingpower (mg/g)	1.24 ± 0.01^b	2.10 ± 0.06^a
Total antioxidants (mg/g)	1.04 ± 0.02^a	0.95 ± 0.02^b
DPPH (%)	52.03 ± 0.81^a	27.24 ± 0.56^b
TTA (mg/g)	1.29 ± 0.08^a	0.62 ± 0.03^b

TTA- Total Titratable Acid

Table 2: Proximate composition of yellow and red fleshed pulp of *C. albidum*

Parameter	Yellow	Red
Protein(%)	4.31 ± 0.02^a	4.13 ± 0.02^b
Crude fiber (%)	1.66 ± 0.01^a	1.59 ± 0.01^b
Fat (%)	0.26 ± 0.00^b	0.27 ± 0.00^a

Brix (%)	10.67 ± 1.15^b	16.33 ± 0.58^a

Means ± standard deviation in the same column with different superscripts are significantly different(p≤0.05)

DISCUSSION

Chrysophyllum albidum fruit pulp is characterized by its colour as the pulp is either yellow or red with the yellow fleshed being sour than the red fleshed. The sour taste can be attributed to higher levels of total phenolics and antioxidants in YFP (1.71 ± 0.06 mg/g and 1.04 ± 0.02mg/g) compared to 1.58 ± 0.02 mg/g and 0.95 ±0.02 mg/g respectively in RFP as shown in table 1. Total flavonoid contents at 2.01 ± 0.02 mg/g as found in YFP is comparable to those found in the pulp of Carpatin (2.22 ± 0.11mg QE/100g) and Andrea (2.87 ± 0.23mg QE/100g) varieties of plum (*Prumus domestica* L.) cultivars as reported by Cosmulescu *et al.* (2015). The total phenols present in both YFP and RFP (1.71 ± 0.06 and 1.58 ± 0.02mg/g) were found to be higher than reported by Mohankumar *et al.* (2019) for the pulp of seven (7) different species of mango (*Mangifera indica* L.) which had values ranging from 0.17 ± 3.79 to 0.56 ± 4.89 mg of GAE/g but lower than that in mandarin pulp (3.90 ± 43.71mg/g) and pulp from different species of clementine (3.11 ± 66.50 to 4.05 ± 123.2 mg/g) (Boudries *et al*., 2012). The levels of the reducing power in both YFP and RFP as shown in table 1 indicates that they have the potentials as good reducing agents in the lipid peroxidation process(Arazo *et al*., 2011) The Vitamin C content in the samples studied (0.29 ± 0.11 and 0.20 ± 0.00mg/g) as shown in table 2 was found comparable to the ascorbic acid content of yellow mombin at 0.27 ± 0.66 mg/g, higher than that in passion fruit at 0.71 ± 2.40 mg/g and pear at 0.0053 ± 0.00 mg/g but lower in that of guava 1.02 ± 0.00mg/g and cashew 2.28 ± 1.68mg/g(Contreras-calderon *et al*., 2011).

Ash content is a quantitative indicator of minerals present. The Ash content in both samples ranged 3.94 ± 0.14 to 4.10 ± 0.10% and were not significantly different but were found lower than 5.73 ± 0.25% as reported in the pulp of *Adansonia digitata* (Sadiq *et al*.,2009) and found higher in the pulp of *Chrysophyllum albidum* 2.29 ± 0.04% reported by (Ibrahim *et al*.,2017).

Fat in both YFP and RFP were quite low when compared to that obtained in the pulp of *C. albidum* 6.97 ± 0.51 reported by (Ibrahim *et al*., 2017) and 6.24% recorded for *Tamarindus indica* (Ishaku *et al*., 2016). The protein content of 4.31 ± 0.02 and 4.13 ± 0.02 found in the YFP and RFP respectively were found higher than 1.53 ± 0.04% found *Adansonia digitate* (Sadiq *et al*., 2009) but lower than that reported for *Chrysophyllum albidum* 7.31 ± 0.46%(Ibrahim *et al*., 2017). Crude fiber aids digestion and both pulps had low values when compared with *Spondias mombin* pulp having 4.2 ± 0.04g/100g (Adepoju 2009). The high moisture content indicates the tendency of the fruit to rot quickly at relatively high temperatures. Carbohydrate content ranged between (21.20 ± 0.16 to 33.66 ± 1.34 %) was higher than 6.43 ± 0.19% as reported by Abraham *et al*.,2019 for fruit pulp of *Balanites aegyptiaca* and lower than that of tamarind pulp 60.02% (Ishaku *et al*.,2016).

This study has shown that the yellow fleshed fruit of *Chrysophyllum albidum* are a rich source of antioxidants showing high levels of flavonoids, phenolics and total antioxidant activity. Therefore, it is suggested that they may contribute to promoting human health as a functional food or a value added ingredient.

ABSTRACT

Unripened soft cheese "warankashi" was made by partially replacing soya milk (SoM) with cocoa powder (CoP) at 0.0%: 100% (A), 2.5%: 97.5% (B), 5.0%: 95% (C) and 7.5%: 92.5% (D) for CoP: SoM respectively. Proximate composition and antioxidants analyses: DPPH, radical scavenging abilities of the cheese were carried out. The sensory evaluation of the samples was done using taste panelists comprising 15 female and 13 male members of staff of the Cocoa Research Institute of Nigeria who are regular consumers of cheese. The proximate chemical components showed significant difference (p<0.05) in protein, crude fat, and total ash content which increased from 4.34% to 5.47%, 16.76% to 26.90% and from 16.15% to 17.44% respectively as the inclusion level of cocoa powder increases. The radical scavenging activities of the cocoa based cheese, FRSA contents also increased from 51.50% to 68.14% and 20.78% to 37.14% respectively as the cocoa powder addition increases. The result of consumer acceptability test shows that sample C (5%: 95%) and D (7.5% :92.5%) were accepted as well as the control sample.

Key words: Warankashi, soya milk, cocoa powder, proximate composition, antioxidants, sensory evaluation

INTRODUCTION

Cheese, a concentrated dairy commodity, either of animal origin or plant origin, is produced by a combination of activities including acid or rennet coagulation or curdling milk, stirring and heating the curd, draining off the whey, collecting and pressing the curd. The cheese is ripened, cured, or aged to develop the flavour and texture (Ayodeji *et al*, 2020, Balogun *et al*, 2016, Lawal and Adedeji, 2013). According to Bodyfelt *et al*. (1988) cheese is a dairy product made by coagulating either whole milk, part-skim (low fat) milk, skim milk, or cream by removing much of the liquid portion while retaining the coagulum and the entrapped milk solids. 'Warankashi' is consumed in its fresh unripened state, fried or used as a meat-analogue in stews and soups. 'Warankashi' is an excellent source of protein, fats and minerals such as calcium, iron and phosphorus, vitamins and essential amino acids, thus making it an important food in the diet of both old and young (Oladipo and Jadesimi, 2012). Cheese made from animal milk is a very good source of animal protein, fat, carbohydrates, ash and moisture and a good source of sodium, potassium and Calcium (Omotosho *et al*., 2011). When it is of plant origin, it also has a very rich nutritional profile.

Cocoa, *Theobroma cacao*, has been widely used in varying applications. Chocolate has been consumed as confection, aphrodisiac, and folk medicine for many years before science proved its potential health benefits (Ackar *et al*, 2013). Cocoa beans are one of the best known sources of dietary polyphenols; the total polyphenol content of the dried fat-free-mass of fresh cocoa beans is around 15–20% and of fermented beans approximately 5% (Wollgast and Anklam 2000). The polyphenol content in cocoa beans depends on their origin and processing, as they are subject to a combination of fermentation and drying treatments, followed by alkalisation and roasting, which affects the polyphenol content and consequently the end product quality (Hii *et al*. 2009). Since cheese of animal origin is costly and rare to come by in developing nations, coupled with its low vitamins C and mineral content, milk was sought from plant origin. This made milk readily available and accessible for the teeming population and her nutrition need. Still, due to effect of processing, milk of plant origin lack capacity to provide adequate mineral content and antioxidants need of the populace. Continous search in solving these nutritional deficiencies gap prompted more research to improve the quality of cheese made from these raw materials. The objective of this project therefore, is to increase utilization of cocoa (cocoa powder) in cheese making, improve presentation and nutritional composition of 'warankashi', an unripened cheese.

MATERIALS AND METHODS

Material Collection and Preparation

Well dried and clean soyabeans was obtained from Oja Oba market in Ibadan while cocoa powder was supplied by the marketing department of CRIN, Ibadan, Nigeria. Alum was obtained from open market in Ibadan and five percent concentration was prepared.

Production of soyabean Milk

Dry, cleaned soyabeans was measured and soaked in water for about six hours before wet milling was done using a hammer mill. Filteration was done through a double-layered muslin cloth, and manually squeezed with a twisting motion to extract most of the milk. The extracted emulsion was pasteurized and stored at 30°C before the production of cheese and used within 24 hours of production.

Production of choco-soy-cheese (cocoa-warankashi) blend

The portion of the sieved milk for warankashi production from the soyabean milk was measured. The variation in the measurement was done according to the method described by Igyor *et al*. (2006). Cheese samples were produced from 1000 mL of soyabean milk with cocoa powder added at varying proportions, to create a ratio of (CoP: SoM) 0:100; 2.5:97.5; 5:95; and 7.5:92.5 (w/w). Alum solution was used as a coagulant. 20 mL of the 5% alum solution was added to each of the milk blends. The method of Ashaye *et al*. (2006) with some modifications was used to produce the cheese. Soyabean milk with cocoa powder blend was transferred into a metal pot. The pot was placed over a slow burning fire and heated till it starts boiling. The milk was kept at the boiling point and the coagulant (20 mL alum solution) introduced until it coagulated and there was a visible separation of curds and whey. The curds and whey were then poured into a clean muslin cloth and the whey was allowed to drain. After a few minutes, the formed curd was placed in a clean container and cut to desired shapes. The cut curd was fried in hot vegetable oil (light frying), allowed to cool and packed in clean air permeable wrappers prior storage on a shelf at room temperature.

Proximate Analysis

The standard method of the AOAC (2000) was used for the analysis of protein percentage, crude fat, ash content, crude fiber, and moisture content. Moisture content was determined after drying at 103 ºC until a constant weight was attained. Protein was determined by the Kjeldahl method (N x 5.84), crude fat was extracted with petroleum ether using Soxhlet apparatus (gravimetric method), ash (gravimetric method), while total carbohydrate quantity was determined by the differences: % carbohydrate = 100- (% protein + % fat + % ash + % crude fiber + % moisture).

DPPH Radical-scavenging activity

Sample Extraction

Five (5) g of fried choco-soy-cheese (warankashi) were uniformly homogenised using the homogenizer with 50 mL of HPLC grade methanol in an ice bath at speed 5 r.p.m for 1 minute and filter under reduced pressure through Whatman No 1 filter paper according to Arabbi *et al*. (2004). The effect of all extracts and standard antioxidants on DPPH radical was estimated according to the method of Blois 1958 reported by Arabbi *et al.* (2004):

DPPH Scavenging Effect %

$$\frac{A_0 - A_1 \text{ x100}}{A_0}$$

Where: A_0 is the absorbance of control and A_1 is the absorbance of extracts or standards.

Free radical scavenging assay

Free radical scavenging activity of cocoa-warankashi samples was determined by the method reported by Re *et al*. 1999. ABTS·+ scavenging effect (%) = ((AB–AA)/ AB) × 100 (2), where, AB is absorbance of ABTS radical + methanol; AA is absorbance of ABTS radical + sample extract/standard. Trolox was used as standard substance.

Sensory Evaluation

Sensory evaluation was conducted using a 9-point hedonic scale and a semi-trained panel comprising 15 female and 13 male members of Cocoa Research Institute of Nigeria familiar with the consumption of cheese. The panelists evaluated the coded samples for colour, taste, flavour, toughness, and overall acceptability. Each sensory attribute was rated on a 9- point hedonic scale (9 = like extremely and 1 = dislike extremely) (Iwe, 2007).

Statistical Analysis

SPSS 20.0 was used to statistically analyze the data obtained from the study. Results obtained in triplicate determinations and subjected to analysis of variance to determine the significant differences among the samples. Means were separated using Duncan test.

RESULTS AND DISCUSSION

The results obtained for the proximate compositions of the samples were significantly different at 95% confidence level (Table 1). The significant difference observed was primarily due to the interaction of cocoa powder with the soya milk used in cheese making. There was an increase in moisture content in all the cocoa-soy cheese samples analysed. The percentage moisture of 18.00% which was the least was observed in the control sample (A: 100 % soy-cheese) and while sample B had the highest moisture content. (CoP: SoM, 2.5: 97.5), 26.48 and thereafter declined for sample C (25.69) and sample D (23.15). There was no significant difference in moisture content of cocoa soy cheese blends B and C. The protein content of the cocoa-soy cheese blends (Table 1) ranged from 16.76% – 26.90%. Sample A had the lowest level of crude protein content, while the highest crude protein content was recorded in sample D. Thus, protein content of choco-cheese increased with increased level of cocoa powder.

Crude fat level ranged from 16.15% – 17.44%. The lowest crude fat content (16.15%) was observed in the control sample (A), while the rest were not significantly different from one another. Fat is important as a source of energy in the human body (Onyeka, 2008). The impact of light frying on the cocoa-soy cheese could partly be responsible for the moderate fat density in the cocoa-soy cheese samples. The ash content in a food material is a measure of mineral elements in food (Balogun *et al*., 2016). It shows a positive increasing trend with the minimum result being 4.34% and highest ash result being 5.47%. This further affirmed the fact that varying inclusion levels of cocoa powder in soya milk was responsible for high mineral content of the cocoa-soy cheese blends. Choco-cheese blends C and D are not significantly different ($p<0.05$) but different from blends B and the control (A).

Table 1: Proximate composition of unripened choco-soy-cheese

Sample	Moisture (%)	Protein (%)	Fat (%)	Fibre (%)	Ash (%)	Carbohydrates (%)
A	18.00^c	16.76^d	16.15^b	0.00^a	4.34^c	44.75^a
B	26.48^a	21.48^c	17.37^a	0.00^a	5.10^b	29.57^b
C	25.69^a	23.87^b	17.28^a	0.00^a	5.39^a	27.77^c
D	23.15^b	26.90^a	17.44^a	0.00^a	5.47^a	27.04^c

Values are means of triplicate determination, ^{abcd}Values in the same column bearing different superscripts are significantly different ($p<0.05$). Legend: A (0:100), B (2.5:97.5), C (5:95), D (7.5:92.5)

Total carbohydrate content of the cocoa-soy cheese blends ranged from 44.75% - 27.04% among samples with added cocoa powder. The control sample had a value of 44.75%. This result indicated that there was a significant difference ($p<0.05$) among the samples and a decrease in the carbohydrate contents of the cheese samples. This result agreed with the position of Balogun *et al* (2016), as carbohydrate decreased with increasing substitution of cow-soya cheese.

Table 2 shows the result of antioxidant capacities of the choco-cheese samples. The DPPH (2,2-diphenyl-1-picrylhydrazyl-hydrate) scavenging effect analysed on the cheese samples revealed an increasing trend with the control sample having least value. It was observed that the DPPH value increased as the portion of cocoa powder increased in the cheese. Highest value (68.14%) was recorded in sample D (7.5: 92.5). The DPPH scavenging effect was significantly different ($p<0.05$) in all samples. Free radical scavenging activity evaluated as ABTS+ cation scavenging effect [2,2-azinobis (3-ethylenebenzothiazoline-6-sulfonic acid)] also increased across all samples of cocoa-soy cheese. Free radical scavenging activity was highest in sample D, followed by sample C, sample B and least in sample A (100% soy-cheese).

Table 2: DPPH and FRSA content of unripened choco-soy-cheese

Sample	% DPPH	% FRSA
A	51.50^{d}	20.78^{d}
B	64.21^{c}	31.74^{c}
C	66.54^{b}	35.35^{b}
D	68.14^{a}	37.14^{a}

Values are means of triplicate determination, ^{abcd}Values in the same column bearing different superscripts are significantly different ($p<0.05$). Legend: A (0:100), B (2.5:97.5), C (5:95), D (7.5:92.5)

Table 3 presents the sensory mean scores of taste panelist who rated the produced cocoa-soy cheese. There were significant differences ($p<0.05$) observed in all the products implying that, there were variations in the test products. This variation is partly attributed to varying inclusion levels of cocoa powder (CoP: SoM) in the blends and partly due to the nature of soya milk itself. For colour or appearance, control (100% soy cheese) as well as sample D (7.5:92.5) were rated best followed by sample B (2.5:97.5) and sample C (5:95), respectively. The cocoa-soy cheese blend with inclusion level of '7.5:92.5' appeared more like meat analogue 'liver', hence the acceptance. This result was at variance with Aworh and Akinniyi (1989) and Igyor *et al*. (2006) substitution resulting to discolouration and cheese analogue led to reduced acceptability. In terms of toughness, no significant differences exist between all the samples. It is opined that cocoa inclusion in the 'warankshi' blend did not adversely impair the anticipated smoothness, firmness and coherence of produced cocoa-soy cheese. A few respondents remarked on brittleness of control sample but rarely noticed in samples with varying level of cocoa inclusion. For taste, cocoa-soy cheese with highest cocoa inclusion was rated best scoring 6.95 while there was no difference ($p>0.05$) with control (100% soya milk), sample B (97.5% soya milk) and sample C (95% soya milk) respectively whereas, flavor across all made cocoa-soy cheese blends were similar (no significant difference). In terms of overall acceptability, 7.5:92.5 cocoa-soy cheese had the highest rating (7.75), followed by 0:100, control, with mean score (7.55), and cocoa-soy cheese 5: 95 (7.05). Cocoa-soy cheese, 'warankashi', (2.5:97.5) had the lowest score (6.70). This investigation shows consumers' willingness to try out seemingly new products. For all the attributes rated, sample C (5:95) and sample D (7.5:92.5) were accepted as well as the control sample.

Table 3: Sensory evaluation of unripened cheese made from cocoa powder soy-milk blend

Sample	Colour	Taste	Flavour	Toughness	Overall Acceptability
A	7.80[a]	5.35[b]	6.60[a]	7.50[a]	7.55[a]
B	6.75[ab]	6.05[ab]	6.70[a]	7.10[a]	6.70[b]
C	6.45[ab]	5.65[ab]	6.95[a]	6.85[a]	7.05[ab]
D	7.30[a]	6.95[a]	7.20[a]	6.35[a]	7.75[a]

Values are means of triplicate determination, [abcd]Values in the same column bearing different superscripts are significantly different ($p<0.05$). Legend: A (0 :100), B (2.5:97.5), C (5:95), D (7.5:92.5)

CONCLUSION

The results from this study show there was an increase in protein, fat, minerals (ash) and antioxidants level as cocoa inclusion increased. This therefore implies the possibility of creating a new product, cheese analogue, for the populace. The nutritional value discovered in producing 'warankashi' by inclusion of cocoa in soya milk blends will improve the well being of the populace from Nigeria and other developing nations. In conclusion, cocoa can be utilized in making functional cheese for categories of people regulating their carbohydrate intake. This can be served as a snack food or component of a meal. Sample C (5%:95%) and sample D (7.5%:95%) cocoa-soy cheese was acceptable to panelist; hence the inclusion of cocoa powder at 5% or 7.5% should be encouraged in production of cocoa-soy cheese.

ABSTRACT

Cashew kernel milk (CKM) was partially replaced with skimmed milk (SKM) in ice cream production. The recipe of the different formulations was: 10 %, 20 %, 30 %, 40 % and 50 % (v/v) (CKM: SKM), while 100 % skimmed milk ice cream served as control. Samples were evaluated for physicochemical parameters like pH, Titratable acidity (TTA), Total soluble solids (TSS) and microbiological stabilities over 3 weeks' storage period. The proximate and sensory characteristics of samples were determined. The TTA, TSS and pH of the ice creams reduced significantly ($p < 0.05$) during storage but less pronounced in samples containing CKM which is concentration dependent. Results showed range of values of 3.12 - 3.93 % protein, 0.48 - 1.07 % crude fibre, 0.66 - 2.29 % crude fat and 80.1 - 82.15 % moisture content. The bacterial and the fungal counts were within standard recommended for ice creams. Sensory evaluation showed significant differences ($p < 0.05$) among the ice-cream samples up to 20 % above which the taste becomes unacceptable. Cashew kernel milk can therefore substitute skimmed milk in ice-cream production.

Key words: Cashew kernel, DPPH, ice-cream, proximate, skimmed milk

INTRODUCTION

Ice-cream remains one of the most cherished dairy products in the world (Choo *et al*., 2010). Most of the ice-creams available in the market are generally poor in natural antioxidants like vitamin C, colors and polyphenols. It is therefore of interest to explore the possibility of improving the nutritional attributes of ice-cream using ingredients with health benefit like fruits, vegetables, nuts, pulses and fibers in line with consumer expectations. Cashew is a tropical tree crop containing pseudo-apple and sickle shaped nut which has appealing consumer traits like flavor, color and nutritional content, especially vitamin C (Emelike and Akusu, 2019). In Nigeria, cashew kernel has seldom been utilized in other food applications as pea nuts (Aroyeun, 2009) despite the tremendous rise in its yearly production (FAO, 2000). About 60 % of cashew kernels are consumed in form of snacks while a low quantity has been used in the production of differently formulated cashew kernel-based snacks. The remaining unutilized portions have been regarded as wastes because of lack of storage facilities. Ice-cream is made from milk ingredients (milk fat and milk solids-not fat), sugar, water, and other optional ingredients such as flavorings, colors, stabilizers and emulsifiers (Schmidt, 2004). The ice-cream flavor and color are normally generated through adding a small amount (i.e. approximately 0.3 % ice cream mix). Based on the nutritional profiles of cashew kernel milk, this study was developed for it to substitute skimmed milk powder in the production of ice-cream with aim of establishing the effect of its partial replacement on the antioxidant profiles and nutritional contents. Microbial stability and its sensory qualities in comparison with the control were also investigated.

MATERIALS AND METHODS

Sample collection

Cashew nuts used for this study were obtained from the CRIN, Ibadan. The nuts were processed to obtain the kernels following the steps for cashew kernel processing.

Production of Cashew Kernel Milk

Milk production from cashew kernel was carried out as described by Adedokun *et. al*., (2014) with some modifications. Roasted cashew kernel was divided into three equal parts of 450 g each and then soaked in 250 ml of portable water for 6 hours. The water was removed and each portion was blended (using Philips HR2000 blender) into slurry at the ratio of 1:6 (w/v) kernel to water. The slurry was filtered with muslin cloth to separate the milk. The supernatant was removed with water; the milk was skimmed together and concentrated into ¼ of the initial volume. The milk was boiled until frothing stopped. The extracted milk was reserved in the fridge for further use.

Cashew kernel milk /skimmed milk ice-cream Production

Varied levels of cashew kernel milk were used to replace skimmed milk at 10, 20, 30, 40 and 50 % CKM / SKM ratio respectively. All the required ingredients such as milk solid non-fat (MSNF), milk fat (MF), milk blends CKM / SKM, sugar, stabilizer, emulsifier blend (CREMODAN) and water were thoroughly mixed, pasteurized at 80 ^{0}C for 30 s, homogenized in a two-stage process, at 13.8 MPa and 3.6 MPa for 5 min using ULTRA _ TURRAX IKA-T25 digital (Werke Staufen, Germany). The ice-cream mix was then rapidly cooled to room temperature and aged at 4 ^{o}C over-night. No flavor was added to the ice-cream mix prior to freezing to avoid any unrelated flavor impact. The mix was whipped using an ice-cream maker (Kenwood, Model: IM 280, UK) at a constant speed for about 20 min, packaged and stored in the freezer frozen at 20^{o}C.

Physicochemical and Proximate Analysis of Ice-cream mix

The ice-cream mix was subjected to physic-chemical analyses such as, pH, Titratable acidity (TTA) and the Total soluble solids (TSS). The pH of the melted ice-cream samples was measured using a pH meter model: 3505 pH meter, Jenway, UK. The percent titratable acidity was determined as described by A.O.A.C. (2012). The TSS (^{O}Brix)) involves the determination of Total Sugar Level*:* The total sugar level (°Brix) of each ice- cream sample was carried out using refractometric method (Soluble solids) using hand Refractometer (Atago Brix 0-32 % Model TM 1600, Gibertini, Italy). The crude protein, fat content, moisture content, ash, crude fibre were all determined according to standard procedure (AOAC, 2012)

Microbiological Analyses

Five (5) g of melted ice-cream samples and the control were each aseptically homogenized in 10 ml of sterile ringer solution; 3 ml of each of the mixture were plated in the different culture media to obtain the number of CFU/g of product. Moreover, decimal dilutions were plated in the same culture media. The microbial groups investigated were total microbial counts of mesophilic aerobic microorganisms, determined in Plate Count Agar (PCA) medium (Oxoid) and incubated at 30 ^{O}C for 48hours under aerobic conditions; total coliforms in violet red bile Agar (VRBA) (Oxoid, 37 ^{O}C), 24 h under aerobic conditions. Lactic acid bacteria was determined using De Manns Rogosa Agar (MRS); Staphylococci using mannitol salt agar (MSA); Moulds were enumerated using potato dextrose agar (PDA) medium (Oxoid). These were evaluated over a three-week storage period.

Organoleptic property

The sensory characteristics of the ice-cream samples were conducted using an acceptance test. Each analysis was performed by 25 untrained panelists drawn from various academic institutions. Sensory attributes of taste color, flavor, and overall acceptability were evaluated.

Statistical Analysis

Data were generated from the means of triplicate determinations with standard deviations (S.D). Analysis of variance (ANOVA) was carried out using SPSS version 23 for Windows (SPSS Inc., Chicago, IL, USA), and the determination of significant differences among treatment means was conducted under Duncan's multiple range tests ($P \leq 0.05$).

RESULTS AND DISCUSSIONS

Variations occurred in the pH of the ice-creams samples at 21-day storage period as shown in Table 1. Sample G had the highest level of acidity while the least was obtained in Sample F. This could be due to the presence of anacardic acid in G as against lactic acid in F. In the ice-cream mix, Sample B was higher in acidity while Sample C had the least acidity. However, the acidity level in the samples assumed an irregular pattern.

Table 1: Physicochemical properties of Cashew kernel ice-cream mix

Sample	pH	% TTA	TSS (^{0}Brix)	SG
A	5.7	-	2.4	1.009
B	4.2	-	4.0	1.015
C	5.9	-	7.0	1.028
D	4.4	-	7.1	1.029
E	5.5	0.268	7.2	1.042
F	6.4	0.268	16.7	1.075
G	4.1	0.266	17.0	1.076

A – 10 %, B – 20 %, C – 30 %, D – 40 %, E – 50 %, F – 100 % conventional milk, G – 100 % cashew milk, TTA - Titratable acidity, SG - specific gravity, TSS - Total soluble solid

The effects of CKM supplementation in the ice-creams were evident from the TSS values. A direct relationship occurred between the CKM and the sugar contents of the ice-cream. The sugar in milk is lactose which is not as sweet as sucrose in cashew which could be responsible for the higher Brix in CKM ice-creams as against the control. The total soluble solids increase steadily and reached the maximum level at the 50 % inclusion in the mix (Table 1).

Table 2: Proximate chemical compositions of cashew kernel ice-cream

Sample Code	Crude Protein	Crude Fat	Crude Fibre	Total Ash	Moisture content	Dry Matter	CHO
A	3.12	2.66	0.08	3.87	80.17	18.31	13.1
B	3.41	2.49	0.21	3.89	81.89	18.61	11.0
C	3.60	2.43	0.43	3.95	80.06	21.35	12.43
D	3.93	2.29	0.36	3.97	80.97	19.76	11.38
E	2.18	2.07	0.14	3.69	81.31	17.62	13.61
F	3.48	2.69	0.25	3.12	81.39	18.58	13.17
G	3.79	2.42	0.39	3.94	82.15	17.85	10.31

A - 10 %; B – 20 %; C – 30 %; D -40 %; E - 50 %; F – 100 % milk; G – 100 % Cashew Milk, CHO - Carbohydrate

The crude fat in the conventional milk ice-cream (Sample F) was higher than in Cashew kernel milk ice-cream (Sample G) as shown in Table 2. This implies that the latter is a more health-friendly ice-cream than the former, more so that the fat in G is more of unsaturated (Aremu *et. al*., 2006) compared to F that contain more of saturated fatty acid (McCance, and Widdowson, 2002). In the mix, fat content decreases with increase supplementation of CKM (Table 2). Similar results were obtained by Tainara *et al*., (2013) who reported a reduction in percentage fat contents of ice-cream produced from orange by products. The Protein content in G was higher than in F probably due to the inherent high protein content of cashew kernel (Aremu *et. al*., 2006). In the mix, the protein content increased with increasing supplementation up to 40 % (Table 2).

In Table 3, the lowest yeast count, after 21 days was observed in Sample E while the highest was in C. The yeast counts in all the samples fall within the acceptable limit for ice–creams. The presence of staphylococcus species was not detected in any of the samples analyzed. The lactic acid bacteria (LAB) were generally not observed in the samples. The total viable counts (TVC) in the samples were also within the acceptable limit, while there were no indications of mould growth, coliform and staphylococcus presence. These are indications that pasteurization was adequate and the cold storage system effective. This study established the safety of the ice-creams for human consumption. The sensory evaluation (not shown) showed an overall acceptable level of 20 % cashew kernel milk supplementation in the ice-cream according to the panelists.

Table 3: Microbiological profiles of ice-cream from CKM / SKM blends

Samples	Yeast count	Staphylococcus count	LAB Count	TVC	Coliform Count	Mould count (Propagules/ml)
A	7.4x10^5	No growth	No growth	4.95x10^6	No growth	No growth
B	5.99x10^7	No growth	No growth	6.10x10^7	2.02x10^7	No growth
C	6.00x10^7	No growth	No growth	7.82x10^7	2.62x10^7	- (no growth)
D	5.84x10^7	No growth	No growth	5.48 x10^7	2.26 x10^7	No growth
E	3.66 x10^7	No growth	No growth	3.13 x10^5	1.53 x10^7	No growth
F	4.80x10^7	No growth	No growth	3.20 x10^7	7.2 x10^6	No growth
G	6.7x10^6	1.10x10^6	1.19 x10^7	5.38 x10^7	6.5 x10^5	4.22 x10^7

CONCLUSION

CKM addition enhanced the physical, chemical and sensory characteristics of ice-cream. CKM could therefore be used as an easily accessible source of natural food supplement.

ABSTRACT

Banana based food product is becoming acceptable both in the rural and urban centres, which is also revel among the nutritionist and consumers. In this study, physical properties of banana and plantain flours and starches from different cultivars were investigated for both food and non-food applications. Six unripe but mature banana and 2 plantain cultivars from which physical properties such as pulp colour, starch and flour yield were measured were also used for starch and flour production. The result showed that all the cultivars studied had bright pulp lightness index (L), good colour difference (ΔE) and good Chroma (ΔC). Obino 1 had the least 54.76 L*, 28.81 ΔE and 22.91 ΔC values. The highest starch yield was recorded in the banana cultivars (9.7%-12.5%) while the highest flour yield of 42.1% was recorded in banana Cv. Saro 14. The study reveal that starch and flour can be both be produced from plantain and banana but banana produce more starch and flour than plantain.*

Key words: Starch, Flour, Plantain and Banana.

INTRODUCTION

Banana is a major food crop which is being produced globally, often used for all *Musa* species. Although genetically, most consumed bananas are hybrid of *M. acuminata* (A) and *M. balbisiana* (B). The edible bananas are classified as diploid (AA and AB), triploid (AAA, AAB, and ABB), or tetraploid (AAAA, AAAB, and AABB) (Soares *et al.,* 2011). Nutritionally, the classification is based on sweetness and starch content. While dessert banana converts almost all its starch into soluble sugar at ripening, plantain do not which in turn affects the taste. Therefore, dessert bananas are consumed raw while plantains are consumed cooked, baked, fried, flour, starch etc. The value addition sensitivity in banana/plantain production is becoming acceptable in other to curb post-harvest loss and increase income generation. The main post-harvest product often accepted in Nigeria is banana flour and starch. Starch is affordable and inexpensive raw materials for commercial production and industrial uses (Daudt *et al.*, 2014). Starch is available in large quantities in major plant sources, this includes plantain and banana. The use of banana and plantain starch should be encouraged for commercial production and industrial usage especially in food industrials, animal feeds and bioethanol.

Banana flour is one of the banana-based intermediate food products which traditional and local production is becoming widely acceptable now. Aside the reduction in the crops post-harvest losses, the nutritional value is revel among the nutritionist and consumers. Also, starch is a very important biopolymer in the food industry, where it performs various functions as thickener, binder, disintegrate, stabilizer, texture modifier, gelling and bulking agent. Starch varies greatly in form and functionality between and within botanical species, and even from the same plant cultivar grown under different conditions (Copeland *et al.* 2009). Although fewer cultivars of bananas and plantains are known and been cultivated due to anthropogenic selection. However, the optimal use of the available cultivars for starch and/or flour production is paramount.

Form and functionality of food products which include starch and flour varies between and within botanical species and cultivars. Determination of plantain and banana starch and flour physical properties is important for successful usage for both industrial and household uses. Thus, this study focused on investigating the physical properties of banana and plantain flours and starches of some available banana landraces in Nigeria. It is believed that the information would be relevant for both food and non-food applications of these plantain and banana products.

MATERIALS AND METHODS

Matured unripe bananas and plantains fruits used for this experiment were harvested 85 days after flowering from National Horticultural Research Institute (NIHORT) Project 4 Banana Germplasm field. Six banana cultivars (Saro, TMBX-5, Medium Cavendish, Saro 14, Dwarf Cavendish and Saro 17) and two plantain cultivars (Obino 1 and Agbagba NFC) were used in this study. Pulp colour of the banana and plantain studied were measured using a colourimeter (Chromater CR 410 Konica Minolta, Sensing Inc., Japan) and the values expressed on the lightness index (L*), colour difference (ΔE) and chroma (ΔC) tristimulus scale. The flour and starch were obtained using Pelissari *et al*. (2013) modified protocol, while each study were carried out in triplicates. Data were analysed using descriptive statistics.

RESULTS AND DISSCUSION

The colour characteristics of cultivars pulp are shown in Figure 1. The lightness index (L*) of the pulp was in the range of 54.76 and 74.70 (Figure 1). This result showed that Obino 1 is having the darkest pulp colour (Figure 1). However, the result recorded in study showed that all the cultivars studied had bright colour starch and flour. Mayasti *et al*. (2021) reported bright colour starches from the cultivars studied. The measurement of colour difference (ΔE) was in the range of 28.81 and 49.83 (Figure 1). Based on the ΔE values, the materials can be recommended for use in products requiring a uniform colour except Obino 1 which has the least L* and ΔE values (Figure 1). The chroma (ΔC) is usually regarded as a measure of colour purity (DeMan, 1999) and had been reported to have inverse relationship with particle size (Desalegn and Hailu, 2020; Prasopsunwattana *et al*., 2009). The chroma (ΔC) of the samples pulp were within the range of 22.91 and 30.30 (Figure 1).

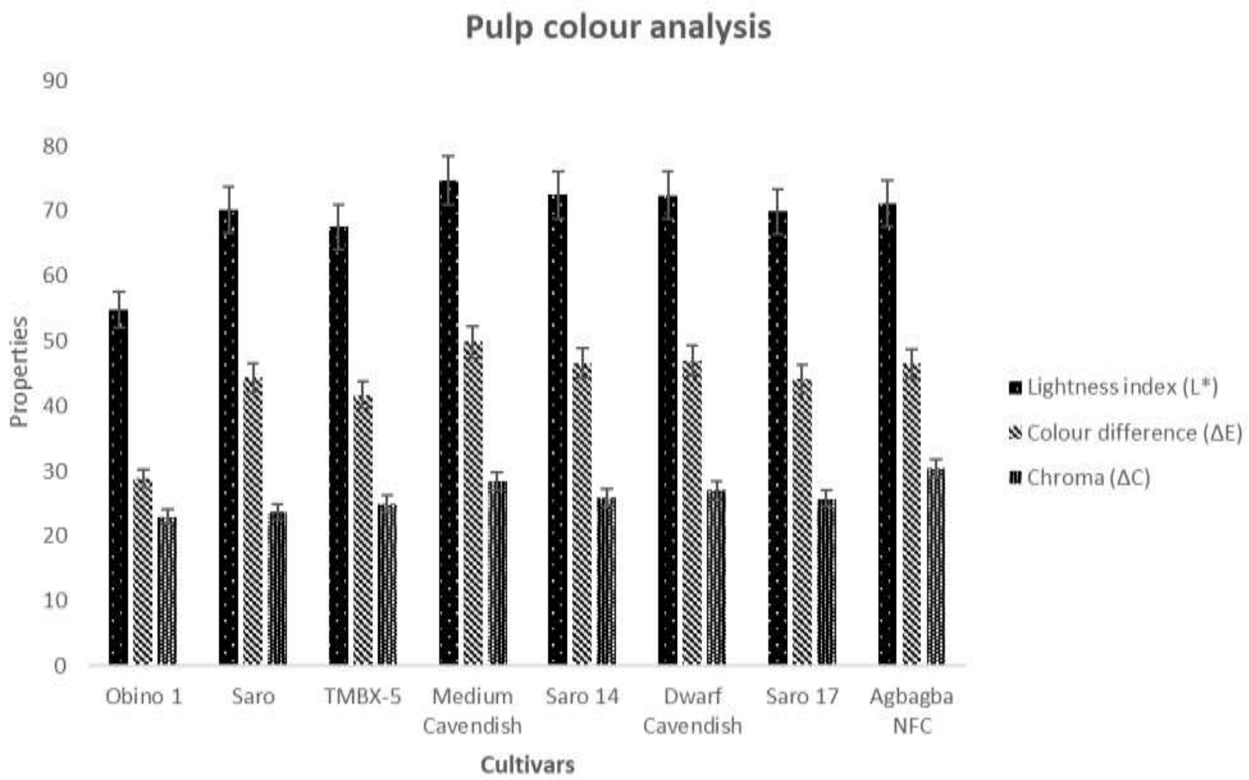

Figure 1: Colour Analysis of the Pulp of the plantain and banana Cultivars studied.

The result of this study showed that higher starch content was extracted from banana cultivars (9.7%-12.5%) compared to plantain (5.6% - 8.7%; Figure 2). The percentage extracted starch yield observed in this study varied slightly from previous studies. Otegbayo *et al.* (2010) reported 14% and 22% starch yield for plantain and banana respectively in the study of the crops starch and physicochemical properties. Daiuto *et al.* (2005) reported that the protocol use in starch extraction often affect the starch extracted quantity and quality. However, banana has been reported to have more extracted starch yield compare to starch yield from plantain cultivars (Eraga *et al.*, 2016; Otegbayo *et al*., 2010).

Also, the highest percentage flour yield (42.1%) was reported in Saro 14 cultivar while the lowest percentage flour yield (23.25%) recorded in this study was observed in Agbagba NFC cultivar (Figure 2). Although, Obino 1 had a closer value of flour yield of 41.18% which had a closer percentage flour yield of 42.1% observed in Saro 14 (Figure 2).

Starch has been reported to vary physicochemical properties within and between species (Zhu, 2014; 2015). Mayasti *et al*., (2021) reported a lowest flour yield in the genotype AAB which plantain (*Musa paradisiaca*) is a AAB genome.

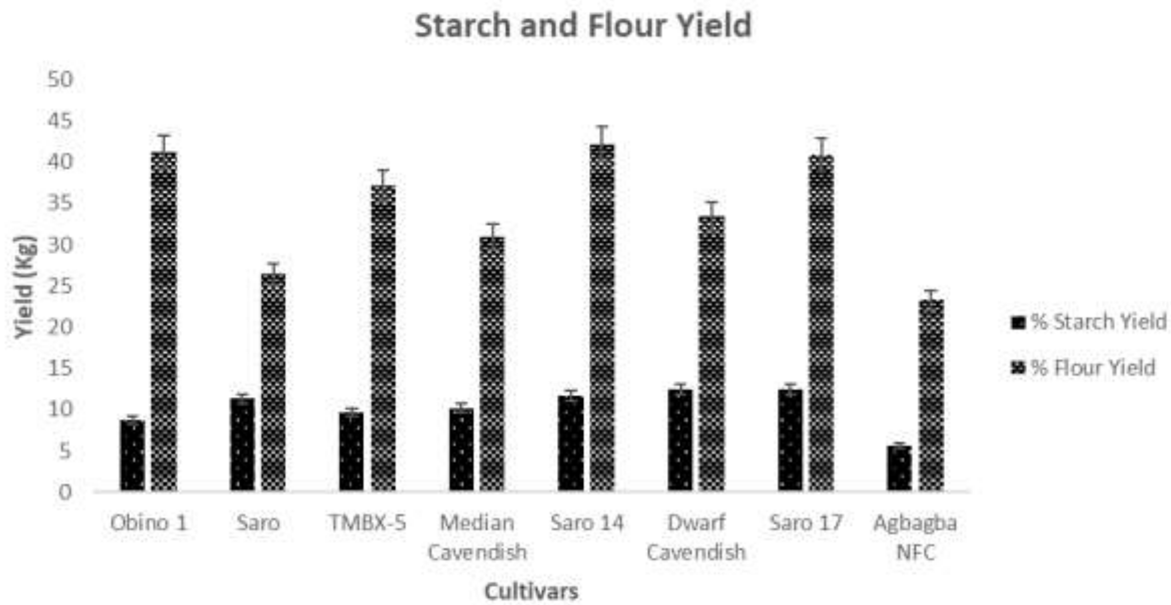

Figure 2: Percentage starch and flour yield of the plantain and banana cultivars studied

CONCLUSION

The utilization of plantain and banana starch and flour is dependent on physicochemical properties. This study showed that the starch and flour extracted the plantain and banana cultivars study had good physical properties. The percentage extracted starch and flour yield was higher in banana compared to plantain extracted starch and flour yield. Generally, the properties and characteristics of the starches and flours showed that they can be used as functional ingredients in food systems for household and industrial uses. However, banana and plantain proper classification is needed so as to group each cultivar in taxons for optimal usage.

ABSTRACT

Economically, the development of biscuits from composite flours is advantageous. The production of cocoa powder, banana flour and wheat flour composite biscuit aims at developing a functional food that is relatively cheap and available. This study focuses on the evaluation of cocoa powder, banana flour and wheat flour composite biscuit in the ratios 5:5:90, 10:10:80,15:15:70, 20:20:60, 25:25:50 and 0:0:100 (as the control) respectively. The biscuits samples were evaluated for their antioxidants and sensory properties using standard procedures. The antioxidants properties results ranged as follows: reducing power (1.05-3.54mg/g), total phenol (1.48-3.79mg/g), flavonoid (0.24-6.8mg/g), and total antioxidant. (2.9-9.91mg/g). The sensory evaluation was also carried out for color, flavor, taste, crispiness and overall acceptability; the results were 5.10 -7.80, 4.20-7.50, 2.90 – 7.50, 4.60– 7.40 and 4.50- 7.70 respectively. Interestingly, sample containing 5% whole wheat flour and 10% each of cocoa powder and banana flour was the best in terms of nutritional and sensory qualities.

Key words: Cocoa powder, anti-oxidative potentials, composite biscuits, nutritional quality.

INTRODUCTION

Biscuits are widely consumed convenient, cheap and ready-to-eat snack for all age group in many countries (Adebowale *et.al*., 2012). Biscuits are mainly produced from 100% wheat flour in the past, but there is limited availability of wheat grains in Nigeria due to the unfavorable climatic condition for wheat cultivation and policies such as the ban on the importation. However, Nigeria has climatic conditions that are suitable for tropical crops such as roots, tubers and cereals. Therefore, consumption of biscuits requires development of an adequate substitute for wheat. This is advantageous because it reduces importation cost by encouraging the use of indigenous crops such as cassava, yam, maize and others that are partially substituted for wheat flour (Satin, 1988). The FAO reported that the utilization of composite flour in various food products would be advantageous economically if the importation of wheat could be reduced or even eliminated, and that demand for wheat based products could be met by the use of domestically grown products instead of wheat (Jisha *et al*., 2008). Composite flour as defined by Milligan *et al*. (1981) is a mixture of flours, starches and other ingredients intended in totally or partially replacing wheat flour in bakery and pastry products. In developing countries such as Malaysia, the use of composite flours had a few advantages ranging from saving foreign currency to promoting high-yielding, native plant species to supply of better protein for human nutrition and better overall utilization of domestic agriculture production (Berghofer, 2000; Bugusu *et al*., 2001). Banana is one of the most consumed fruits in tropics and subtropics, and in terms of economical value it is the number five agricultural crop in world trade. The worldwide production of bananas in 2012 was 139.2 million tonnes (FAOSTAT, 2012). Besides, world banana exports are projected to reach almost 17.9 million tonnes in 2011.

Musa spp being one of the cheapest crops to produce and the cost of its production is less than most other staples. Besides being used solely as dessert, banana fruit may be processed into pulp-liquid fruit, canned slice, deep-fried chips, toffees, fruit bars, brandy and etc. (Kachru *et al.,* 1995; Morton, 1987). An estimate of 35% loss of the production of bananas was reported for developing countries (FAO, 1987). This is due to the fact that banana is a climacteric fruit and due to the habit of consuming ripe fruit, large quantities of this commodity are lost during its commercialization and post-harvest handling. A new economic strategy is to process green bananas into dried flour and incorporate the flour into various innovative products so as to encourage consumption of banana and thus contributing to the health of humans (Ovando-Martinez *et al.,* 2009; Ramli *et al.,* 2010). Green banana flour contains up to 61.3-76.5 g/100 g starch on dry basis, a percentage comparable to that in the endosperm of corn grain and the pulp of white potato; apart from starch, Green banana Flour is high in total dietary fiber (6.28-15.54 g/100 g dry basis), which participates in the hypocholesterolaemic effect (Horigome *et al.,* 1992; Mota *et al.,* 2000; Zhang et al., 2005). This is a new economical strategy includes the production of unripe banana flour which are incorporated into various innovative products such as slowly digestible cookies (Aparicio-Saguilan *et al.,* 2007), high-fibre bread (Juarez-Garcia et al., 2006) and edible films.

Cocoa, in recent times has become the target of increased scientific research, due to its pro-health properties (Bogumiła and Jolanta, 2019). Fresh cocoa bean contains about 32–39% water, 30–32% fat, 10–15% protein, 5–6% polyphenols,4–6% pentosans, 2–3% cellulose, 2–3% sucrose, 1–2% theobromine, 1% acids and less than 1% caffeine. Three types of flavonoids dominant in cocoa beans are proanthocyanins (circa: 58%), catechins orflavan-3-ols (circa: 37%) and anthocyanins (circa: 4%) (Khan and Nicod, 2012; Khan *et al*.,2014). The high polyphenol content of cocoa and its wide presence in many food products, makes it particularly interesting both from a nutritional point of view and health (Khan *etal*.,2014; Da Silva Medeiros *et. al*., 2015; Cinquanta *et al*., 2016; Giacometti *et al*., 2016; Tsang *et al*., 2019). Polyphenols are not only antioxidant properties, but also affect sensory properties such as colour and taste (Kothe *et al*., 2013; Zyzelewicz *et al*., 2016; Dabas, 2016; Giacometti *et al*., 2014). The aim of this study is to evaluate the effect of cocoa powder incorporation in banana wheat composite biscuit.

MATERIALS AND METHODS

The banana fruit was purchased from Ologede market, Podo, Ibadan. While the other ingredients such as wheat, coco powder were purchased from Apete market, Ibadan.

Sample preparation

Banana fruits were peeled with a sharp knife and the peels were separated from the flesh using a blunt knife. The flesh of the fruits was then cut into smaller sizes and sundried for 2 days until they attained a constant weight. The peels were then ground with a blender (VTCL, Spark), and the powder sieved through a 500 μm diameter sieve. The powder was then stored in self-sealed paper bags and kept in a cool dry place until utilization.

Formulation of the biscuits

Six samples of the biscuits were formulated. The formulation of the biscuit produced from composite blends of cocoa powder, banana flour and whole wheat flour were in the ratios 5:5:90, 10:10:80,15:15:70, 20:20:60, 25:25:50 and 0:0:100 (as the control) respectively.

Sensory analysis

A consumer acceptance evaluation was performed with a panel of 20 untrained tasters, to whom biscuits were given in random order. Tasters were asked to evaluate different parameters, such as appearance, odor, taste, flavor, texture, overall liking, and purchase predisposition on a 9-point hedonic scale (1-extremely dislike, 9 -- extremely like)

Determination of antioxidant capacity

Sample extraction was done according to the method described by Bloor (2001). Total phenolic content of the extracts was determined colorimetrically, using the Folin–Ciocalteu method as described by Singleton et al. (1999). Total flavonoid content was determined based on the spectrophotometricmethod (Jia *et al*., 1999). Antioxidant Capacity, Ferric Reducing/Antioxidant Power Assays were determined following the methods described by Katalinic *et al.* (2005).

Statistical analysis

The results of chemical, colour, antioxidant and sensory analyses were subjected to one-way analysis of variance (ANOVA) with Duncan's post hoc test at a 95% confidence level. Values obtained by the consumer acceptance test were analyzed by in SPSS software package, version 20.

RESULTS AND DISCUSSION

Sensory Characteristics of Biscuit Samples

The sensory characteristics of biscuit samples are shown in Table 1. The color, flavor, taste, crispiness and overall acceptability ranged from 5.10 -7.80, 4.20- 7.50, 2.90 – 7.50, 4.60– 7.40 and 4.50- 7.70 respectively. The results obtained are significant different at 95% confidence level ($P<0.05$). The colour of the biscuit samples reduced with increased inclusion of the cocoa powder and banana flour, Sample WF had the highest acceptability followed by the sample with 5% inclusion of cocoa powder and banana flour. Similar finding was obtained by Adejumo *et al.,* (2020). However, sensory characteristics are of great importance in the consumers' point of view (Ghadge *et al*., 2008), Higher expectation was therefore placed on the overall acceptability of the composite biscuits. The overall acceptability of samples CBWF5, CBWF10, CBWF25 and WF fell within the like region, while others did not. Among the composite biscuits samples, panelists preferred the sample that its whole wheat flour was substituted with 5% cocoa powder and 10% banana flour.

Table 1: Sensory evaluation of cocoa powder- banana wheat composite biscuits

Samples	Colour	Flavour	Taste	Crispiness	Overall acceptability
CBWF5	6.30^{bc}	5.90^{ab}	6.80^{ab}	7.00^{a}	6.80^{ab}
CBWF10	5.20^{bc}	6.20^{a}	6.00^{b}	6.10^{ab}	6.30^{bc}
CBWF15	5.50^{bc}	4.20^{c}	2.90^{d}	5.10^{b}	4.50^{e}
CBWF20	5.10^{c}	4.50^{bc}	4.00^{cd}	4.60^{b}	4.70^{de}
CBWF25	6.60^{ab}	6.00^{ab}	4.60^{c}	6.10^{ab}	5.60^{cd}
WF	7.80^{a}	7.50^{a}	7.50^{a}	7.40^{a}	7.70^{a}

Mean values having different superscripts within a column are significantly different ($p<0.05$)

Anti-oxidative Potentials

The reducing power of the cocoa powder-banana and wheat flour biscuit ranges between 0.56-4.30 with the CBWF25 having the highest value and CBWF10 was having the lowest value. The total phenolic compounds of the cocoa powder-banana and wheat flour biscuit rangedbetween 1.48 – 3.79 with CBWF15 having the highest value but not higher than the WF. The flavonoids of the cocoa powder-banana and wheat flour biscuit ranges between 0.56-4.30. Sample CBWF20 had the highest value followed by CBWF25.

Table 2: Anti oxidant values obtained for cocoa powder banana and wheat flour biscuit

Samples	Reducing power (%)	Total phenoic compounds (%)	Flavonoids (%)	Total Antioxidants (%)
CBWF5	1.11^{b}	2.60^{c}	3.61^{ab}	5.27^{a}
CBWF10	0.56^{b}	2.40^{d}	0.95^{b}	3.40^{a}
CBWF15	1.82^{b}	3.64^{b}	0.66^{b}	5.69^{a}
CBWF20	1.05^{b}	1.86^{e}	6.80^{a}	4.11^{a}
CBWF25	4.30^{a}	1.48^{f}	3.81^{ab}	2.92^{a}
WF	1.58^{b}	3.79^{a}	0.93^{b}	6.86^{a}

Mean values having different superscripts within a column are significantly different ($p<0.05$)

CONCLUSION

This study has shown from the results obtained that nutrient dense biscuits can be produced by substituting wheat flour with 5% cocoa powder and 5% banana flour. Biscuits produced from 90% wheat flour and 5% cocoa powder and 5% banana flour substitution was most acceptable to the panelist. Thus, consumption of cocoa powder, banana composite and wheat biscuits would increase the anti oxidant intake which help to prevent diseases and increase the utilization of cocoa and banana in developing countries including Nigeria.

ABSTRACT

The concentration of phenolics and fibres in the orange pomace suggest that it could serve as an ingredient in novel food. Increase in consumers' demand for functional foods with natural origin like pomace is also on the increase. However, the possible toxicological effect has to be investigated. Orange pomace, wheat bran and soyameal of different ratio were subjected to extrusion (5Kg per cycle) at fixed cooking temperature (110 °C) and screw speed (290 rpm). The extrudates were tested on forty male Wistar rats for toxicity for 28 days. Data were analysed using ANOVA at $\alpha_{0.05}$. Tested diets on Wistar rats resulted in lower weight gain which was at variance with control diet. White blood cells, creatine and glucose showed no significant difference between rats fed control and tested diets. The absence of toxic effect on the rat suggested that the food could be consumed for its health promoting benefit in addition to eliminating environmental pollution by orange pomace.

Key words: Orange pomace, soya meal, wheat bran, toxicological parameters

INTRODUCTION

Orange pomace is the waste that remains after processing oranges to juice, wine or other products. The wastes from this processing, including peel, seeds and pulp, which make up nearly 50% of unprocessed fruit, are a possible source of valuable byproducts (Gowe, 2015). Orange pulp is rich in fibre. The fibre has superior quality than others because of the occurrence of minerals, sugars, including bioactive substances like polyphenols, flavonoids and carotenes (Fernandez-Gines *et al*., 2003). The phenolic compounds of citrus pomace could undergo enzymatic oxidation at various stages of processing. Dehydration under suitable conditions enables reduction in water present and water activity in the products. The prevention of oxidative enzymatic reaction and the development of microorganisms prolong the storability of the products (Mhiri *et al*., 2015). Previous work has involved the use of pomace in the manufacture of several intermediates which include the production of compounds and solvents in flavours and colognes, as components in paints, cosmetics and animal supplements. Zaker *et al*., (2016) reported that incorporation of orange pomace up to 10% in cookies preparation increased nutritional value, especially in fibre, physical quality and general acceptance of biscuits. Our previous study developed and characterized the fibre of extruded whole food from orange pomace, soyameal and wheat bran hence this study to evaluate the possible toxicity of the food.

MATERIALS AND METHODS

Sample Preparation

Orange pomace was obtained after juice production from sweet oranges (Agege variety) at the juice processing pilot plant of the National Horticultural Research Institute, Jericho, Ibadan, Oyo State. The pomace was dried at 60 ± 2 °C, ground with a laboratory mill (500 µm) and kept in an airtight 250-micron polyethylene until use. Soyameal and Wheat bran was purchased from an Agro processing supplier, Oluyole Estate, Ring Road, Ibadan, individually ground to 500 µm and packed for further use.

Extrusion cooking

Extrusion cooking was performed according to the modified Huang and Ma (2016) method. Mixtures of wheat bran, soybean meal and orange pomace with different mixing ratios (Table 1). These were the adjudged best in our previous study.

Table 1: Formulations of orange pomace, soyameal and wheat bran extruded

Sample	Orange pomace	Soyameal	Wheat bran
P2	17	44	39
P3	5	80	15
P4	10	80	10

Animal requirements

Ethical consent to animals was obtained from ACUREC(UI-ACUREC/App/2016/027), University of Ibadan before study. Wistar albino rat (*Rattus norvegicus*) of approximate weight of 70- 80 g was used. The animals were obtained from the Department of Veterinary Pathology, University of Ibadan. The venue of the experiment was the Department of Animal Sciences, University of Ibadan. Forty (40) animals were used for the study.

Animal treatment and organ examination

After one week of acclimatization, the 40 rats were separated into four groups as follows: the first group which was control received basal diet while the other three with different ratio of orange pomace, wheat bran and soyameal (17: 39:44, 5:15:80, 10:10:80) % were fed for 3 weeks. The experimental animals were observed closely for up to 21 days, thereafter biological and hematological tests were carried out.

Nutritional evaluation on rats fed with the tested blends

During the experimental period (3 weeks), the consumed diets were recorded every day, and body weights were recorded every week. Nutritional evaluation of various diets was performed by determining body weight gain% (BWG%), feed efficiency ratio (FER), feed conversion ratio (FCR) according to equations described by El-Sayed *et al*. (2014) .

Hematological analysis

About 2 ml of blood samples was taken with heparinized capillary tubes to determine the hematocrit value according to Rodak (1995) method. Total red and white blood cells, Hemoglobin strength, mean corpuscular volume, mean corpuscular hemoglobin concentration and mean corpuscular hemoglobin concentration were estimated by the method reported by Lawal *et al*. (2015).

Method of Euthanasia/Disposition of animals

At the end of the study, animals certified fit were donated to the Zoological garden of the University of Ibadan.

RESULTS AND DISCUSSION

Feed Efficiency/weight gain

At the expiration of the experiment, weight gain and food consumed by the rats fed on the experimental diets were lower than the control (Figure 1). There were no significant differences in food intake between control and tested diets, but weight gain was significantly different. Rat fed with food blend of 17% pomace, 44% soyameal and 39% wheat bran had the highest weight gain while those fed with 5 % pomace, 80% soyameal and 15% wheat bran had lowest weight gain. Lower weight gain from the tested food suggests that the food could be considered to make a difference in the onset and progression of overweight and obesity. This is in line with findings of Keenan *et al*., (2006) that fibre is able to reduce body weight gain or decrease weight gain. This has been attributed to various factors such as soluble fibre, which produces glucagon-like peptide (GLP-1) and peptide TY when fermented in the colon. The two intestinal hormones take part in inducing satiety, decrease energy intake and also decrease metabolizable energy.

Rat fed with control diet were able to digest the diet better than the other tested diets which resulted in increased digestion and absorption of nutrients. Soluble dietary fibre in form of neutral detergent fibre was more in the control diet than the tested diets (Table 2) leading to more absorbed nutrients and weight gain. The same trend was observed in the Feed efficiency ratio and conversion ratio (Figure 2 and 3). The result was comparable with the findings of Rashad and Moharib (2003) of lowered nutritional parameters as a result of high fibre feed fed to rat. The trend could be due to the distribution of soluble and insoluble fibre fraction; hemicellulose, cellulose and lignin present in the tested and control diets.

Hematological parameters

The result of the hematological parameters shows that Packed Cell Volume (PCV) count to be from 35.67 to 37.33% (Table 2) and is within clinical range for rat. The highest PCV was obtained for diet P2 followed by diet P3. No significant difference was observed between the control (P0) and the tested diets. The PCV known as hematocrit (Ht) or (HCT) or erythrocyte volume fraction (EVF) is the percentage (%) of red blood cells in the blood. According to Isaac *et al*. (2013) PCV is involved in the transportation of oxygen and absorbed nutrients. Increased PCV shows better transport and therefore increases the primary and secondary polycythemia.

A higher PCV value for rats fed with the study diet shows that diets are suitable for transporting oxygen and nutrients. The hemoglobin (HGB) value of the albino rat fed the diet P2 (12.63) was the highest, followed by P3, P0 and finally P4. No significant variation ($p > 0.05$) was observed among HGB of rat fed with the food. The result suggests that hemoglobin is sufficient for the albino rats for its physiological function of transporting oxygen to the animal tissues to oxidize red blood cells (RBC). Rats fed control and experimental feed (P0, P2, P3 and P4) were not significantly different. Diet P2 had the highest mean RBC count (6.00×10^{12}) while P4 had the least (5.66×10^{12}). These values are in the laboratory range for rat (Sharp *et al*., 1998) and suggested no toxic effect of experimental diet on the rat.

Table 2: Hematological variables of rat fed control and experimental diets

Diet	PCV (%)	HGB (g/dl)	RBC (x 10^{12})	WBC (x 10^9)	Plt	Lym	Neu	Mo	Eos
P0	36.33^a	12.07^a	5.95^a	5283^a	171667^a	65.33^a	30.33^a	1.67^a	2.67^a
P2	37.33^a	12.63^a	6.00^a	5950^a	191000^a	66.33^a	31.00^a	1.33^a	1.33^a
P3	37.00^a	12.33^a	5.96^a	6400^a	156000^a	70.33^a	25.33^a	2.00^a	2.33^a
P4	35.67^a	11.97^a	5.66^a	6100^a	133333^a	66.67^a	30.67^a	1.33^a	1.33^a

Value are mean of three replicates followed by different letters in the same column are significantly different.

PCV – packed cell volume, HGB – Heamoglobin, RBC –red blood cell, WBC – white blood cell, plt – platelet, lym - Lymphocyte, Neu –Neutrophils, Mo -Monocycte, Eos –Eosinophils. P0 = control, P2 = 17 % pomace 44% soyameal 39 % wheat bran, P3 = 5 % pomace 80% soyameal 15 % wheat bran, P4 = 10 % pomace 80 % soyameal 10 % wheat bran.

Red blood cells are used for transportation of oxygen and carbon dioxide in the body (Isaac *et al.* 2013); hence, low red blood cell count signifies a decrease in the level of oxygen transported to the tissues and carbon dioxide returned to the lungs (Soetan *et al*., 2013).

Highest white blood cell (WBC) was recorded for rats fed with diet P3 (6400 x 10^9) which was not significantly different ($p > 0.05$) from other diets. The main roles of white blood cells are defending the body by phagocytosis against attack by foreign organisms, combating infections, production, transportation and distribution of antibodies in the immune response. The result of the study is within the clinical range suggesting that the albino rats were able to generate antibodies in the course of phagocytosis with high degree of resistance to diseases (Soetan *et al*., 2013). It will also encourage their compliance to natural ecology and disease dominant conditions as supported by Iwuji and Herbert (2012).

Platelet count for rat fed with the diets was between 133333 and 191000, the highest from diet P2 while the lowest was from diet P4. There was no significant variation observed among the control and the test diets ($p > 0.05$) The difference in the level could be as a result of variation in the type (dose, structure, soluble, insoluble) of dietary fibre in the diets (Rashad and Moharib, 2003). Table 4.8 also corroborates the findings showing difference in the Dietary fibre fraction. Platelets are involved in blood clotting, the platelet concentration was within the clinical range, suggesting that the process of clot formation (blood clotting) will be quick in the event of an injury in the control diet and on tested diets. Lymphocyte value for the control and test diets were from 65.33 % to 70.33 %. The highest from Diet P3 and lowest from diet P0. No significant variation ($p > 0.05$) obtained from the diets. Maximum neutrophilis were recorded for the blood samples of rats fed P2 (31%), followed by diet P4 (30.67%) while diet P3 had the least (25.33%). No significant variation ($p > 0.05$) was observed among the diets. The result shows no toxic effect on the blood samples of rat fed the experimental diets.

CONCLUSION

The absence of toxic effect on the rat suggested that the food could be consumed for its health promoting benefit in addition to eliminating environmental pollution by orange pomace.

ABSTRACT

The use of floral preservatives has been pertinent to the longevity of cut flowers. This study focuses on the influence of Aloe vera gel solutions and silver thiosulphate solutions used as floral preservative on the vase life of Heliconia cut flowers. The experiment was carried out in the plant physiology laboratory, Floriculture programme, National Horticultural Research Institute, (NIHORT); Ibadan, Nigeria (7°25" N and 3°52" E). Five treatments were used; 0.5 and 1.0 mM silver thiosulphate (ST1 and ST2), 2% and 4% Aloe vera solutions (AV1 and AV2) and water as control (CO). Each treatment was supplemented with 3% w/v sucrose and consists of ten replicates. Fresh Heliconia flowers were harvested early in the morning from the Floriculture garden, washed and uniformly cut as appropriate for the experimental use. The experiment was arranged in a completely randomized design with four replicates. Results showed that there were significant (P<0.05) different in application of the floral preservative treatments the as compared to the control on the vase life of the Heliconia cut flowers as well as other parameters analyzed. Longer vase life (12 days) was recorded for AV1 and AV2 as compared with the control that stayed for 6 days. There was no significant difference in the relative fresh weights of the cut flowers with the different treatments as compared with the control except on day 12. The use of organic floral preservatives such as Aloe vera gel can effectively prolong the vase life of Heliconia vase life as compared with silver thiosulphate.

Key words: Post-harvest, longevity, ornamental cut flowers, organic.

INTRODUCTION

Cut flowers naturally do not have long vase life. Without any form of support, their vase life ranges from 1 – 4 days depending on the plants, its maturity, cultivar, physiological condition, postharvest handling, etc. The reason for its short vase life is because once detached from the parent plant, there is no more supply of any form of nutrients, water and every other essential support causing their flowers and leaves to wilt as a result of unavailable resources that serves as food (Shokalu *et al*., 2018). Other contributory factors include water stress, air embolism, vascular blockage, microbial accumulation and contamination. Heliconias (Golden Torch) are exotic brightly beautiful plants with mostly yellow bracts common in Nigeria and many tropical regions of the world. Heliconia cut flowers have a vase life of about 6 days as they have sturdy bract that help to withstand postharvest handling (Akintoye *et al*., 2018). Silver thiosulphate is an effective ethylene antagonist and such helps to arrest senescence in plants. Aloe vera contains antimicrobial properties. The use of silver thiosulphate (STS) as well as Aloe vera for floral preservatives has been shown to improve the longevity of cut flowers (Adebayo *at al*., 2017, Vehniwal and Abbey, 2019). In Nigeria, cut flower is one of the major industries in floriculture. Therefore, prolonging the vase life of cut flowers has been one of the challenges that is being investigated. The use of floral preservatives has been studied to show that they can promote cut flowers longevity for a period of time by facilitating increased nutrient uptake in the solution, delayed senescence, reduced vascular occlusion and microbial accumulation (Elhindi, 2012; Shokalu *et al*., 2018). Therefore, the aim of this experiment is to evaluate the effect of silver thiosulphate and aloe vera gel preservatives on the longevity of Heliconia cut flowers.

MATERIAL AND METHODS

Plant materials

Heliconia (Golden Torch) flowers were obtained from the floriculture garden in the institute (7°25"N, 3°52"E). Flowering stems of *Heliconia spp.* with four to five open bracts were harvested in the early morning from the floriculture garden. The leaves on the lower section of the stems were removed. The stems were washed under running water to remove dirt. The stems were cut to uniformity of 30 cm and placed in the already prepared floral preservative solution. Vase solutions were not changed throughout the experiment.

Experimental design

Five treatments were used as floral solutions for the study: 0.5 and 1.0 mM Sliver thiosulphate (STS) solutions (STS1 and STS2), 2 and 4% (v/v) *Aloe vera* gel solutions (AV1 and AV2) and water as control (CO). The experiment was arranged in a completely randomized design (CRD) with ten replicates under a temperature of 25 ± 2ºC, 70% relative humidity and 150 µmol m^{-2} s^{-1} light intensity from cool-white fluorescent lamps with a light/dark cycle of 12/12 hours. Data collected was analyzed using Analysis of Variance (ANOVA) while the significant differences among treated means were computed using least significance difference (LSD) test at 5% level of significance.

Relative Fresh Weight and Relative water content

The relative weight was calculated as a ratio, a spike from each treatment was weighed at intervals. Relative water content (RWC) from each sample was determined according to the method described by. To measure the RWC, 2 – 3 excised petals per plant were weighed (fresh weight, FW) and placed in water for 6 hours to allow them reach full turgidity, thus, the turgid weight (TW) was determined. The leaves were then dried at 60°C for 24 hours and their dry weight (DW) obtained. With these, the RWC was calculated using the formula:

%RWC = [(FW – DW) / (TW – DW)] × 100

Vase life

Vase life was determined as the time period for which a spike of cut flower retained 50% fresh flowers. The wilting and bending of the petals is also an index of the vase life of cut flowers.

RESULTS AND DISCUSSION

Relative Fresh Weight:

The fresh weight of the cut flowers showed a declining trend over time in all the treatments. There was no significant difference in the fresh weight of cut flowers up till day 9. By day 12 there was a significant difference (P<0.05) in the cut flowers in respect to the treatments with the lowest value recorded by the control (40.60) and the highest value recorded by AV2 as shown in Figure 1. There was no significant difference among the treatment except the control at day 12. The turgidity of cut flowers is an important factor of their longevity. Treatments of cut flower with lower relative fresh weight tend to lose their turgidity which invariably resulted to their low vase life.

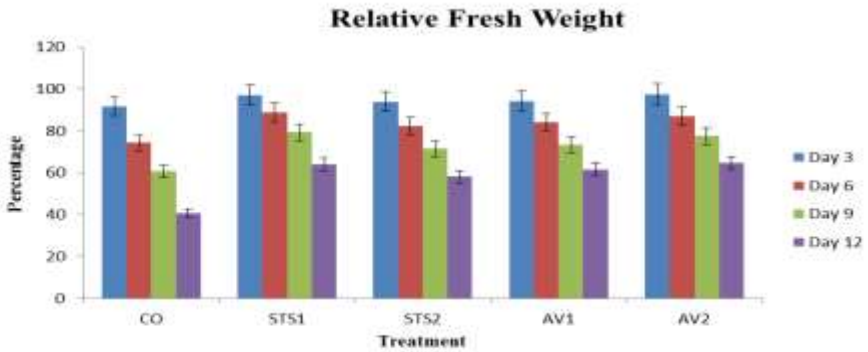

Figure 1: Effect of treatment on the relative fresh weight of Heliconia cut flowers

CO: Tap water (control); STS1: 0.5 mM Silver thiosulphate solution; STS2: 1.0 mM Silver thiosulphate; AV1: 2% Aloe vera; AV2: 4% Aloe vera

Relative Water Content

The relative water content is an also index indicating the water holding capacity of the plant organs and shows the ability of the plant to withstand water stress conditions. Figure 2 shows that there was a significant (P≤0.05) difference in the cut flowers in relation to water content. The AV1, AV2 and STS1 were not significantly different. The highest relative water content value was 51.70 by AV2 while the lowest value was 32.40 by the control. This correlates the report of Shokalu *et al.*, 2019, on the relative water content exhibited by 4% Aloe vera gel solution on the cut flowers of Heliconia.

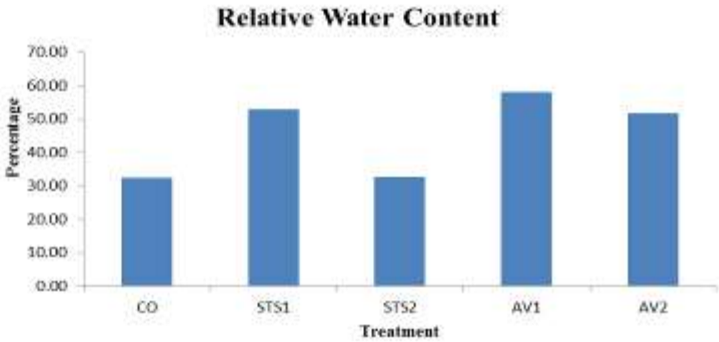

Figure 2: Effect of treatment on the relative water content of Heliconia cut flowers

CO: Tap water (control); STS1: 0.5 mM Silver thiosulphate solution; STS2: 1.0 mM Silver thiosulphate; AV1: 2% Aloe vera; AV2: 4% Aloe vera

Vase life

There was significant difference in the vase life of the cut flowers. As shown in figure 3, CO had a vase life of 6 days while ST1 and ST2 had a vase life of almost 9 days. AV1 and AV2 had the longest vase life compared to other treatments with a vase life of almost 12 days.

The vase life of cut flowers is the most important parameter when considering the longevity of cut flowers. Floral preservation has been very effective in delaying senescence thus extending vase life of cut flowers (Sedaghathoor *et al*., 2020). Loges *et al*., 2013, also reported that the postharvest durability of heliconia was 13 days. In this study, the use of aloe vera and STS solution extended the vase life of Heliconia cut flowers up to 12 days compared to the control.

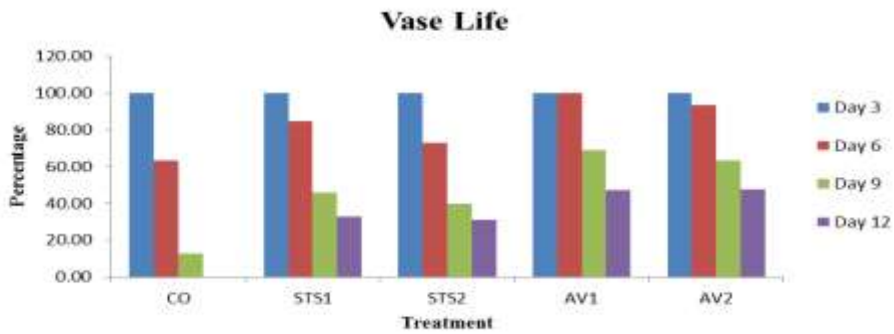

Figure 3: Effect of treatment on the vase life of Heliconia cut flowers

CO: Tap water (control); STS1: 0.5 mM Silver thiosulphate solution; STS2: 1.0 mM Silver thiosulphate; AV1: 2% Aloe vera; AV2: 4% Aloe vera

CONCLUSION

This study has showed that Aloe vera and STS floral preservative solution were effective in improving the longevity of the *Heliconia* cut flowers.

INDIGENOUS ZERO-ENERGY STORAGE METHODS OF FRUITS AND VEGETABLES IN NIGERIA: A REVIEW

Rosulu, H.O., Selesi, O.S. and Adanlawo, A.O.
Department of Agricultural Technology, Yaba College of Technology, Lagos, Nigeria.
*Corresponding author's email: olawale.selesi@yabatech.edu.ng

ABSTRACT

Fruits and vegetables are best consumed as soon as they are harvested, as they tend to quickly decline in freshness, flavour and nutritional qualities under storage conditions. Advances in science and technology has largely benefited the food storage industry as more food, especially fruits and vegetables, can now be stored for much longer while retaining most of their nutritional value as well as their original flavour to satisfy the nutritional requirements of the ever-expanding world population. These storage technologies, apart from being expensive to set up, require a very high energy source garnered from electricity in order to properly function. This is not feasible in a developing country like Nigeria that has poor electricity supply. In order to curb huge post harvested losses usually associated with fruits and vegetables, especially in developing countries like Nigeria, indigenous zero-energy storage methods, that are efficient and effective, are suggested.

Key words: Zero-energy, storage methods, fruits, vegetables

INTRODUCTION

Temperature is the most important limiting-criteria in the storage of fruits and vegetables as varying temperature levels results in rapid respiratory activities, which is the main cause of fruit and vegetable metamorphism (Lei Ji *et al*, 2011). New physical technologies used in the storage of fruits and vegetables are very effective at elongating their shelve life as well as preserving the freshness of these fruits and vegetables. Some examples of these technologies, as highlighted by Lei Ji *et al*. (2011), are: Low Temperature Storage and Fresh-Keeping Technology; which uses continuous and constant low temperature to weaken respiration and prolong storage time, Controlled Atmosphere Storage and Fresh-Keeping Technology; which uses the principle of gas rationing to preserve fruits and vegetables, Pressure Regulating Storage and Fresh-Keeping Technology; which manipulates atmospheric pressure in a storage room to reduce or inhibit microbial activities thus preserving fruits and vegetables, Ionizing Radiation Storage and Fresh-Keeping Technology; which is an advanced technology used in sterilizing fruits and vegetables making and preserving their shelf live in the process. Other examples are Ozone Storage and Fresh-Keeping Technology as well as High-Pressure Electrostatic Field Storage and Fresh-Keeping Technology. These storage technologies, apart from being expensive to set up, require a very high energy source garnered from electricity in order to properly function.

Electricity is gold in Nigeria, especially in rural areas where the bulk of fruits and vegetables are produced. Apart from its epileptic supply, the initial cost of purchasing physical storage facilities such as refrigerators as well as power generating set to power them, coupled with the continuous cost of fuel to run these generating sets as well as spare parts, are very expensive and out of reach to the low-income subsistence fruits and vegetable farmers, making them rely almost solely on indigenous zero-energy storage methods which mimics the principles of those earlier mentioned in order to cut their post-harvest losses. Once leafy vegetables such as African spinach, water leaf, bitter leaf, pumpkin leaf etc are harvested, they deteriorate quickly under warm and dry environmental conditions. In order to curb huge post harvested losses usually associated with fruits and vegetables, especially in developing countries like Nigeria, indigenous zero-energy storage methods that are efficient and effective are discussed below.

MATERIALS AND METHODS

Materials for the review were sourced from secondary data in journals and online.

Indigenous Zero-Energy Fruits and Vegetables Storage Methods

Bulk Ambient Temperature Storage

The vegetables are harvested after which the root is cut off and the stem is gently washed with sterilized water. The washed vegetable is carefully bunched up to about 50 cm diameter and the bunched stem is then dipped unto a bucket of water filled to about three-quarter capacity. A thin black polythene sheet is used to cover the vegetables and the tied closely to the bucket in a way as not to expose the vegetables in any way to conserve moisture. To keep the vegetable moist, water is sprinkled on the leaves daily. The filled vegetable bucket is kept away from sunlight and in the coolest place possible. This technology requires zero-energy and the leafy vegetables can remain fresh for up to 6 days under this condition. (NSPRI, 1982).

Storage in Clay Pots with Jute Bags at Ambient Temperature

Clay pots are washed and placed on a firm support so that their bottom do not touch the ground. Wet jute bags that have been sterilized (through boiling) are placed at the bottom of the pot. A wire gauze is then placed on the bag. The roots of the vegetable are cut and the leafy parts are washed with sterilized water. The washed vegetables are placed on the wire gauze inside the pot. Another layer of wire gauze is placed on the vegetable, which is then followed by another layer of sterilized wet jute bag. The jute bags should be kept moist all the time. (NSPRI, 1982).

Storage in Vegetable Baskets

Well ventilated vegetable baskets made out of raffia are laid with sterilized jute bags after which a wire gaze is placed on the jute bag. The root of the vegetable is cut and the vegetable is washed with portable water. (NSPRI, 1982).

On-farm Shed

A shed, is sited in a section on the farm that is not prone to flooding. The shed, made out of bamboo, should be of dimension 5m x 4m x 3m. Slated bamboo is used to make the sides of the shed to a height of 1.5 m while wire netting is used to complete the other half. The longer side of the shed is constructed in a way so as to face the direction of the wind. Raffia palm is used to make the roof of the shed and the floor can be cemented to make cleaning easy. In more urban areas, concrete can be used to make the floor instead of ordinary cement while timber that has been treated can be used for the sides and corrugated zinc or asbestos are used to make the roof. A 10m x 5m 3m sized shed has enough capacity for up to 10 tonnes of fruits. (NSPRI, 1982).

Pot-in-Pot Evaporative Cooler

A clay pot of about 65 cm in height and 8 mm in thickness is used to completely coat the clay pot and a polythene bag is wrapped around the coated pot. The coated pot is then placed into another pot slightly larger than itself, leaving a space of about 7 cm all around the two pots. Riverbed sand is used to fill the space in between the pots. The sand should be periodically watered to keep moist at all times. Fruits and vegetables are stored inside the inner pot, covered with an appropriate lid and the pot is placed in a cool ventilated place away from sunlight. (NSPRI, 1982).

Metal-in-Pot Evaporative Cooler

The metal-in-pot evaporative cooler is another zero-energy storage method used in developing countries like Nigeria, especially in semi-urban areas. Used beverage tins, large enough to accommodate a substantial quantity of fruits and or vegetable are placed inside a slightly bigger clay pot which has been filled with riverbed sand. The space in between tin and the clay pot is also filled with riverbed sand to serve as an insulator. Fruits and vegetables are stored inside the tin and covered with an appropriate lid. The sand inside the clay pot should be periodically watered to keep moist. The clay pot should be covered with an appropriate lid and placed in a cool dark place away from sunlight. (NSPRI, 1982).

Metal-in-Block Evaporative Cooler

Where large quantities of fruits and vegetables are to be stored using the evaporative cooler zero-energy technology, a metal-in-block evaporative cooler, which is a large-capacity evaporative cooler can be constructed. An area of land that is not flood-prone is selected for the citing the structure. A square metal tank is constructed measuring 1.2m x 1.2 m x 1.2m with a door measuring 63 cm by 51 cm having a thickness of 3 cm on the frontal side. Around this metal tank, a foundation is dug, measuring 1.4 metre square and a depth of 23 cm, after which 23 cm brick blocks are laid around the foundation and 2 cm aggregate concrete is poured into the foundation to make the plinth. Four blocks are placed on the constructed plinth to serve as a base upon which the tank is centrally placed. Blockwork is then built around the metal cube sitting on the plinth with a space of about 10 cm between the cube and the blockwork which is filled with riverbank sand and watered periodically to keep moist. Fruits and vegetables are stored inside the metal cube to minimize post-harvest losses due to spoilage. (NSPRI, 1982).

CONCLUSION AND RECOMMENDATIONS

Considering the huge limitations; inadequate storage infrastructure, inadequate access to finance and especially poor electricity, faced by fruit and vegetable farmers in storing their harvest, especially in developing countries such as Nigeria, cost effective storage methods for fruits and vegetables which are indigenous, efficient and requires zero-energy have been devised by the NSPRI. Although, these indigenous zero-energy methods may not favourably compete with advanced fruit and vegetable storage methods that mentioned earlier which requires huge capital and constant electricity to set up and run, they however, have demonstrated great potentials as they help to store fruits and vegetables for a considerable period of time thereby, significantly reducing post-harvest losses due to spoilage. All levels of government; federal, state as well as local government should, through the relevant agencies and research institutes, priotize the design and fabrication of indigenous storage facilities for fruits and vegetables. Thus, National Centre for Agricultural Mechanization (NCAM) and National Stored Products Research Institute (NSPRI) should be well funded. Efforts of the Federal Government should be geared towards improving rural electrification as well as constructing rural access roads. In conclusion, it is recommended that the role of Agricultural Extension Officers, who are the first contact with farmers, be rejuvenated. This rejuvenation should be coupled with training and re-training on ingenious storage methods for fruits and vegetables.

ABSTRACT

Despite the huge production of yellow pepper, there is scarcity due to high postharvest fruit loss, hence the need to establish appropriate harvest stage (mature green, half ripe and fully ripe) and suitable storage medium (jute bag, plastic basket, and polyethylene bag) to extend shelf life. The experiment was a 3 × 3 factorial in a completely randomized design with three replications. Data were collected on weight loss at four day intervals for 28 days and was calculated as the difference of initial and final fruits weight expressed in percent, postharvest decay was evaluated based on visual observation for decay symptoms at 7 day intervals for 28 days, and shelf-life (time in days the stored fruits show 50% decay after 28 days of storage). Data were analysed using Analysis of Variance. Among the storage media (jute bag, plastic basket, and polythene bag), fruit harvested at half ripe stage lost the least weight (1.12 %, 1.50% and 1.09%) respectively, it also had the least decayed and the most preserved fruits. In all the three maturity stages, the fruits stored in plastic basket although lost the highest weight, but were the least decayed and most preserved. The result suggests that the optimum maturity stage for harvesting yellow pepper would be half ripe stage. Also, plastic baskets should be used as the storage medium for preserving yellow pepper fruits.

Key words: Maturity Stage, Storage Medium, Yellow Pepper, Pepper Fruit and shelf life.

INTRODUCTION

Pepper belongs to the family Solanaceae, genus *Capsicum*. Records show that out of thirty species only five have been domesticated (Nwokem, *et al*., 2010). Fruit features such as shape, size, colour, flavor, spiciness, and so on are used to classify Capsicum species (Bosland, 2012). Among the many varieties grown, yellow pepper is grown in several places of the world. It is among Nigeria's most essential fruit vegetable crops. Despite the huge production of yellow pepper there is scarcity due to high postharvest fruit loss. Most farmers harvest pepper only when it is fully ripe, at this stage of harvest fruits may spoil easily and there will be loss in both quality and shelf life. Different qualities, such as surface colour, fruit firmness, and so on, should be considered as indicator to establish the optimal harvest time Tadesse (2002). Furthermore, several storage materials are used as medium for storage of pepper fruits, but the appropriate material for pepper shelf life harvested at various stages of maturity is not fully established. Hence the need to determine the optimum maturity stage for harvesting yellow pepper and to ascertain the effective and affordable local storage medium for improving the postharvest quality of peppers yellow pepper.

MATERIALS AND METHODS

The yellow pepper seedlings were purchased from local pepper producers in Nsukka market, Enugu State. The seedlings were planted at the Department of Crop Science's Teaching and Research Farm in Nsukka, Nigeria, (U.N.N). The pepper plants' growth was tracked until they reached maturity. The fruits were gathered at three stages of maturity: mature green (MG), half ripe (HR) and fully ripe (FR) and taken for further studies in the Department of Crop Science's Teaching and Research Laboratory at U.N.N. In CRD, the experiment was a three-fold factorial replicated 3 times. The factors were the three stages of maturity MG, HR, and FR and the three storage media (Jute sac, plastic basket and perforated polyethylene bag). Total of 90 clean fruits of a uniform size were used. The fruits were randomly grouped into batches of 30 fruits according to the three maturity stages. Ten fruits out of each were randomly assigned to each of the three different storage media and stored under room temperature for 28 days. Data were collected on weight loss at a 4-day interval for 28 days and was determined by the difference of initial weight and weight at the time of measurement expressed as percentage. Fruits were visually evaluated for signs of deterioration at seven-day intervals for 28 days. Samples that showed decay were recorded and discarded. The shelf-life of the pepper was evaluated and was taken as time when the stored fruits demonstrate 50% postharvest decay after 28 days, a large number of them are regarded to have terminated their lifespan. Using SPSS software version 7, data was subjected to analysis of variance. According to Obi the F-LSD was used to separate the means at 5% of probability (2002).

RESULTS

Table 1 shows that half ripe fruits had the least percentage weight loss (PWL) across the three storage media; jute (3.68%), plastic basket (5.50%) and polythene bag (3.15%). Plastic basket, among the three storage media had the greatest PWL across the three stages of maturity; FR (6.83%), HR (5.50%), and MG (6.38%) while polythene bag had the lowest PWL; FR (4.42%), HR (3.15%), and MG (4.15%). Throughout the storage period the PWL of all the fruits harvested at the three stages of maturity stored in the three media increases progressively. Table 2 shows that Half ripe fruits had the least percentage postharvest decay (PPD) in jute (18.4%), in plastic basket (13.8%) and in polythene bag (27.0%). Basket, among the three storage media had the lowest PPD across the three stages of maturity; FR (24.6%), HR (13.8%), and MG (21.0%) while polythene bag had the highest PPD; FR (44.2%), HR (27.0%), and MG (40.6%). Throughout the storage period the PPD of all the fruits harvest at the three stages of maturity stored in the three media increases progressively. Half ripe fruits had the highest percentage shelf life in jute (59.40%), in plastic basket (85.66%) and in polythene bag (35.72%) (Table 3). Basket, among the three storage media had the highest percentage shelf life across the three stages of maturity; FR (41.78%), HR (85.66%), and MG (56.00%) while polythene bag had the lowest shelf life; FR (15.84%), HR (35.72%), and MG (18.16%). Throughout the storage period, the pepper fruits harvested at the three stages of maturity stored in the three media progressively decreased in their preservability.

Table I: Main effect of storage medium and maturity stage on weight loss of yellow pepper fruits

% Weight loss (days)									
Storage medium	Maturity stage	4	8	12	16	20	24	28	Mean
	FR	2.14	4.02	4.34	5.23	5.90	6.52	7.34	5.07
Jute Sac	HR	1.12	2.78	3.56	3.59	4.37	4.68	5.66	3.68
	MG	1.31	3.86	4.61	4.77	5.37	5.64	6.09	4.52
Plastic	FR	2.31	5.45	7.20	7.26	7.82	8.42	9.38	6.83
Basket	HR	1.50	3.22	5.91	6.03	6.53	7.11	8.18	5.50
	MG	1.99	4.58	6.62	6.86	7.37	8.07	9.08	6.38
Perforated	FR	2.11	2.95	3.98	4.58	5.12	5.84	6.37	4.42
Polythene	HR	1.09	2.56	2.72	3.07	3.66	4.13	4.77	3.15
Bag	MG	1.25	3.57	3.94	4.22	4.86	5.35	5.87	4.15
	LSD(0.05)	0.013	0.013	0.010	0.013	0.572	0.013	0.044	

FR = fully ripe, HR = Half ripe, MG = Mature green, LSD =least significant differences of means ($p < 0.05$).

DISCUSSION

The higher percentage weight loss in pepper fruits harvested at fully ripe stage is the same with findings of Monerizzaman *et al.,* (2009). This could be caused by the rise in transpiration rate which may be aided by worn out epidermal layer (Antonial *et al.,* 2007). Lowest PWL observed in fruits stored in polyethylene bag could be due to the confinement of moisture around the produce by polyethylene bag. This increases the relative humidity, reduces transpiration, and promotes post-harvest decay (Nyanjage, 2005). The higher percentage postharvest decay observed in fully ripe is the same with the report of Ciccarese *et al.,* (2013). This may be as a result of higher rate of respiration, softening of tissues that predispose the fruits to deterioration Bayoumi (2008). The progressive increase in PPD with days could be as a result of accelerated respiration and other catabolic activities which bring about senescence (Ciccares *et al.,* 2013).). The lower percentage shelf life observed in fully ripe as well as in matured pepper could be due to higher respiration rate, plus the presence of immature cuticle without protective wax respectively.

Table 2: Main effect of storage medium and maturity stage on postharvest decay of yellow pepper fruits

Storage medium	Maturity stage	Postharvest decay (days) 0	7	14	21	28	Mean
	FR	00	20	30	45	55	30.0

	HM	00	07	14	23	25	13.8
	MG	00	10	20	30	40	21.0
Perforated Polythene Bag	FR	00	26	50	65	80	44.2
	HM	00	15	30	40	50	27.0
	MG	00	25	40	50	70	40.6
	LSD(0.05)		4.30	10.07	22.32	24.12	

FR=fully ripe, HR= Half ripe, MG= Mature green, LSD= Least significant differences of means (5%) level.

Table 3: Main effect of storage medium and maturity stage on shelf life of yellow pepper fruits

Storage medium	Maturity stage	%Shelf Life in Days 0	7	14	21	28	Mean
	FR	39.0	32.0	28.0	25.7	22.8	28.84
Jute Sac	HR	70.0	63.0	56.0	56.0	52.0	59.40
	MG	49.0	42.0	38.0	31.5	28.0	37.70
Plastic Basket	FR	53.0	46.9	42.0	39.0	28.0	41.78
	HR	100	93.0	86.0	84.0	65.3	85.66
	MG	70.0	63.0	56.0	49.0	42.0	56.00
Perforated Polythene Bag	FR	26.9	19.9	14.0	11.4	07.0	15.84
	HR	46.7	39.7	32.7	31.5	28.0	35.72
	MG	28.0	21.0	17.8	15.2	08.8	18.16
	LSD(0.05)	23.21	14.01	14.55	11.99	09.45	

FR=fully ripe, HR= Half ripe, MG= Mature green, LSD= Least significant differences of means (5%) level.

CONCLUSION

The study concluded that the optimum maturity stage for harvesting yellow pepper is at half ripe stage. Also the best medium was plastic basket and it appears to be effective in improving the postharvest quality of peppers.

ABSTRACT

Postharvest losses, caused by poor handling of perishable crops like plantain poses serious threats to food security in Nigeria. Hence, the need for capacity building of stakeholders on improved plantain postharvest handling techniques. The study was carried out at the National Horticultural Research Institute (NIHORT), Ibadan, Nigeria during a stakeholders' workshop organized in partnership with the Institute of Tropical Agriculture (IITA), Ibadan, Nigeria. Stakeholders along the plantain value chain were invited from across the southwestern zone and were trained on improved plantain post-harvest handling techniques. Participants were subjected to pre- and post-training knowledge assessment at the beginning and end of the workshop, respectively. Information was obtained from 53 trainees with the aid of structured questionnaire and data were analyzed using descriptive and inferential statistics. Results revealed that majority (71.1%) of the trainees were female with mean age of 44±12 years, educated (90.0%) and were either farmers (20.8%) or traders (20.8%). Post-knowledge mean scores of trainees were higher than their pre-knowledge mean scores in all sessions considered during the training. Estimates of the T-test revealed significant difference in trainees' pre- and post-training knowledge scores for postharvest technology ($t=-3.644$, $p<0.01$); food processing and preservation methods ($t=-1.901$, $p<0.1$) and production of plantain-based composite flour ($t=-5.750$, $p<0.01$). The findings imply that participation in training is a viable tool for improvement of knowledge and adoption of technologies among stakeholders. Therefore, more training should be organized for stakeholders for easy dissemination of improved technologies.

Key words: Perishable crops, plantain, plantain-based composite flour, postharvest handling, pre- and post-evaluation

INTRODUCTION

Plantain (Musa spp.) is a giant herb that is cultivated in humid forest and mid-latitude zone of sub-Sahara Africa (Amah et al., 2020). It is believed to have originated from South East Asia. However, a remarkable diversity of plantain exists in sub-Sahara Africa (Akintade et al., 2016). Plantains are known to be good sources of starch and energy (Dankyi et al., 2007; Akinyemi et al., 2010). It is largely planted by small holder farmers and plays a major role in food security and income generation for millions of poor rural regions around the world especially in African and Latin American countries including Nigeria (Adejoro et al, 2010; Edeoghon and Okoedo-Okojie, 2011; Amah et al., 2020).

However, one of the major constrains of plantain production is post-harvest losses (Ajayi, 2018). According to Atanda et al., (2011), postharvest losses are caused by factors categorized into primary and secondary causes. Primary causes are factors that directly impact the fresh produce to cause deterioration, whereas the secondary causes are indirect factors that facilitate the primary causes to increase deterioration (Atanda et al., 2011). The secondary causes are mostly human decision related factors such as poor harvesting, and inappropriate postharvest handling and management practices that facilitate biological deterioration. In Nigeria, plantain postharvest losses can range from 5% (Adewumi et al., 2009; Olayemi et al., 2012) to as high as 40% (Morris et al., 2019). These losses assume considerable economic and social importance. That is why perishable commodities such as plantain need very careful handling at every stage so that the deterioration of produce is restricted as much as possible during the period between harvest and consumption.

To circumvent such losses, there is need to build the capacity of stakeholders on proper postharvest handling of plantain such as improved storage, value addition and preservation with a view to enhancing the shelf-life and diversifying the product base. To this end, stakeholders along the plantain value chain were trained on plantain postharvest handling techniques and in particular processing of plantain-based composite flour thereafter, the effect of the training on participants' knowledge was evaluated. This study therefore described the socioeconomic characteristics of the trainees; examined the pre- and post-training knowledge of trainees on plantain value addition and lastly determined the change in knowledge of trainees on plantain value addition as influenced by the training.

MATERIALS AND METHODS

The study was carried out at the National Horticultural Research Institute (NIHORT), Ibadan, Nigeria during a stakeholders' workshop organized in partnership with the Institute of Tropical Agriculture (IITA), Ibadan, Nigeria. Stakeholders along the plantain value chain were invited from across the southwestern zone and were trained on improved plantain post-harvest handling techniques which include the production of plantain-based composite flour. Participants were subjected to pre- and post-training knowledge assessment at the beginning and end of the workshop, respectively. Information was obtained through the use of structured questionnaire administered to 53 trainees. Data were analyzed using descriptive (frequency, percentage ad mean) and inferential (T-test) statistics.

RESULTS AND DISCUSSION

Socio-demographic characteristics of trainees

As observed on Table 1, majority (71.1%) of the trainees were female which was quite impressive because in the past, trainings of this type were usually male dominated. The mean age of the participants is 44±12 years and most of them (20.8%) were either farmers or traders. More than 90.0% of the trainees have formal education indicating that they would be able to comprehend the teachings and apply the skills acquired during the capacity building and empowerment programme.

Table 1: Socio-demographics characteristics of the trainees

Variable	Percentage	Frequency (n=53)
Sex		
Male	28.3	15
Female	71.1	38
Age		
21-30	15.1	8
31-40	26.4	14
41-50	30.2	16
>50	28.3	15
Mean	44.55

Clergy	1	1.9

Expectation from the workshop

Results on Table 2 revealed that more than 80.0% of the trainees looked forward to acquiring skills/knowledge on plantain production techniques (such as how to increase production, tackle production constraints as well as plantain sucker multiplication techniques) during the capacity building programme. Others intended to gain more knowledge on value addition to plantain.

Table 2: Participants' expectation for the training programme

Expectation	Frequency	Percentage
More knowledge /experience on plantain production techniques	39	81.1
Value addition	2	3.8
No response	8	15.1
Total	53	100

Difference between participants pre- and post-training knowledge score for postharvest technology

Estimates of the mean values as displayed on Tables 3-6 shows the difference between the participants' evaluation scores before and at the end of the training, while the t-test values indicate that there was significant increase in the knowledge score on the different modules; postharvest technology (Table 3), food processing and preservation methods (Table 4) and production of plantain-based composite flour (Table 5) before and after the training ($p<0.01$, $p<0.1$ and $p<0.01$, respectively). Combining the scores, results revealed that the trainees acquired significant knowledge during the capacity building workshop (Table 6) which may likely improve their food processing and preservation methods especially for plantain.

Table 3: Difference between participants pre- and post-training knowledge score for postharvest technology

Score type	N	Mean value	Df	t-value	Sig.
Pre-score (before training)	53	2.8491	104	-3.644	0.000
Post-score (after training	53	4.3585			

Table 4: Difference between participants pre- and post-training knowledge score for food processing and preservation methods

Score type	N	Mean value	Df	t-value	Sig.
Pre-score (before training)	53	3.6321	104	-5.750	0.000
Post-score (after training	53	7.1321			

Table 6: Difference between participants overall score (pre- and post-training knowledge)

Score type	N	Mean value	df	t-value	Sig.
Pre-score (before training)	53	10.0000	104	-4.702	0.000
Post-score (after training	53	15.7736			

CONCLUSION

The study revealed that most of the trainees were educated and economically active, and would be able to comprehend lessons/lectures during the training. At the end of the training, they were able to acquire knowledge on postharvest technology, food processing and preservation methods and particularly the production of plantain-based composite flour. Participation in training is a viable tool for improvement of knowledge and adoption of technologies among stakeholders. Therefore, more training should be organized for stakeholders for easy dissemination of improved technologies.

TILLAGE, POULTRY MANURE, AND VARIETY EFFECTS ON CARROT (*DAUCUS CAROTA*) STORAGE AT AMBIENT LABORATORY TEMPERATURE

Anozie, C.C and Baiyeri, K.P.

Department of Crop Science University of Nigeria, Nsukka, Nigeria

Corresponding author's e-mail: chukwunyere.anozie@unn.edu.ng

ABSTRACT

The experiment was carried out at the Laboratory in the Department of Crop Science, University of Nigeria, Nsukka. The study was to evaluate the storage potential of the two carrot varieties, under ambient laboratory temperature. Two carrot varieties (Touchon Mega and kurado) were subjected to a post-harvest study; Six (6) roots were harvested from each treatment combination. It was further divided into two and replicated 3 times, which gave rise to a 2 x 2 x 3 in completely randomised design (CRD). One part of each treatment was dipped in tap water (unsterilized) for 5mins and the second part of each treatment was dipped in saline water (at 10% dilution) for 5mins. (10% of salt was dissolved in water i.e 10g of salt = 100ml of water; which was used for the sterilisation). Weight loss was recorded and the results showed that the roots dipped in saline water could only stay in storage for 3-4 days while roots dipped in tap water stayed up to 9-11 days in storage. From the results of the experiment, it could be concluded that carrots washed with salt should be consumed before the fourth day while those washed with tap water should be consumed before ninth day.

Key words: Carrot, tillage, poultry manure, variety, storage

INTRODUCTION

The modern carrot, a highly nutritious cool season root crop native to Afghanistan, which remains the centre of diversity of *Daucus carota* was domesticated from the wild carrot (Simon *et al.,* 2008). Carrots are a valuable crop, particularly in locations where they thrive, such as Asia and neighbouring towns. The edible section of the carrot, which is effectively a swelling base of the taproot that includes the hypocotyls, is commonly grown annually. It grows mostly in Nigeria's northern regions, and as a result, it has been designated as a northern crop, and has been grown in northern states such as Kaduna, Kano, and Plateau over the years (Orakpo 2010). The crop is so vital that its production and yield should be improved, examined, and given significant research attention; however, this can only be done if the appropriate production and storage variables are available. This can be accomplished by conducting research into the most efficient and improved methods of carrot production and storage.

Carrots are the greatest vegetable sources of all the vitamins and nutrients needed in the body. Carrots help in some of the body's basic functions such as:

1. Boosting immunity (especially among older people).
2. Reducing photosensitivity (Beta-carotene protects the skin from sun damage).
3. Helping to heal minor wounds and injuries: raw carrot or boiled are applied on cuts as an antiseptic to prevent infection.
4. Reducing the risk of high blood pressure.
5. Cleansing the liver and when consumed regularly, can help the liver excrete fats and bile.
6. Fighting bronchitis.
7. Fighting infection (vitamin keeps cell membranes healthy, making them stronger against disease-causing microorganisms.
8. Improving muscle, flesh and skin health.
9. Helping fight anemia.
10. Reducing acne
11. Improving eye health.

Carrots can be stored in the refrigerator for up to a month if stored properly. To prevent condensation from forming, wrap the carrots in a paper towel and then place them in a bag in the refrigerator, or use a perforated plastic bag. Excess moisture will cause them to rot. Cut off carrot greens, place carrots in a container with lid and cover completely in water. Keep container in the refrigerator, changing the water ever 4-5 days.

MATERIALS AND METHODS

Two carrot varieties were harvested from a field experiment for the post-harvest study. The harvested roots were subjected to a post -harvest study in the Crop Science Teaching and Research Laboratory University of Nigeria Nsukka. The study was to evaluate the storability of each variety under varying manure rate and tillage system; and to determine the longevity of the two varieties after soaking in saline water. Six (6) roots were harvested from each treatment combination from the field. It was further divided into two and replicated 3 times, which gave rise to a 2 x 2 x 3(2 varieties, 2 tillage systems and 3 levels of Poultry manure) in completely randomised design (CRD). One part of each treatment was dipped in tap water (unsterilized) for 5mins and the second part of each treatment was dipped in saline water (at 10% dilution) for 5mins. (10% of salt was dissolved in water ie 10g of salt = 100ml of water; which was used for the sterilisation). The roots were put inside a paper bag and was kept in the laboratory and data were collected on weight changes at 2 days' intervals.

RESULTS

The Result of the experiment in Table 1 evidently showed that carrots dipped in tap water could stay more than 10 days while the once dipped in saline water could stay only for less than 6 days. The table also showed a rapid loss of water as the number of days increases in both the sterilized and unsterilized conditions. Significant differences were observed in the 2nd day on tillage while on the effect of manure it was observed in the sterilized condition in all the days (2,4,6days) recorded. The ridge system recorded higher loss of water in value of 38.5% while the bed had 37.4% weight loss in day 10. The table showed that carrots dipped in saline water also had higher percentage weight loss in the ridge tillage system in Day 4 and Day 6 with 18.9% wt loss and 31.0% weight loss respectively; it can also be observed that at Day 8 the carrot had all rotten. At Day10 in the manure, 0t/ha had the highest percentage of water loss with 40.8% weight loss while 5 tons/ha had lowest loss of water with 34.2%wieght loss in the roots dipped in tap water. While those dipped in saline water showed the highest loss of weight in Day 6 with 10tons/ha manure having the highest percentage loss of 32.2%. In the effects of variety Kurado had 39.0% water loss at Day10 which is the highest while Touchon Mega had 36.9% water loss in the carrot dipped in tap water. The table also revealed that the carrots dipped in the saline water showed that Tmega had more loss of weight than kurado with 30.8%.

DISCUSSION

Carrots during storage undergo a complex series of physiological and biochemical events involving changes in post-harvest quality (Hewett, 2003). Temperature and relative humidity are important factors that affect the quality and shelf life of vegetable crops. However, most fruits and vegetables are washed with salt (Sodium Chloride) before eating them to kill microorganism which the fruit or vegetables might have contacted during transportation or marketing. This study therefore attempted to answer the storability question of the two carrot varieties. Carrots washed with saline water was observed to shrink and rotten faster than those washed with tap water. They stayed stored in lesser days (5-6days after placement) and those washed with tap water stayed longer (10-12 days after placement). This could be attributed to the effects of osmosis, which states that "water moves from area of low concentration to area of high concentration through a semi-permeable membrane". Water moved from the internal root system of the carrot to the environment which caused shrinkage of the roots. High temperatures are also known to promote enzymatic catalysis and lead to biochemical breakdown of compounds in fruit and vegetables. (Kays, 1999). There was an increasing trend in the weight loss with the

ISSN: 2814-0508

advancement of storage periods; the rate of weight loss was much higher in carrots washed with saline water when compared with those washed with tap water. Although there was a non-significant difference between the two carrot varieties, Kurado variety was observed to have lower value in all the parameters measured for storability.

CONCLUSION

It can be concluded that, to enhance carrot storage carrots are to be washed with ordinary water. Carrots washed with salt should be consumed before the fourth day while those washed with tap water should be consumed before ninth day.

ABSTRACT

Postharvest storage life of lettuce (Lactuca sativa) in response to rates of inorganic fertilizer and polyethylene bag colours were evaluated during a seven-day storage study. Two field experiments, each comprising four rates of NPK 20:10:10 and supplemented with potassium nitrate or calcium nitrate were conducted. The storage study combined the fertilizer treatments and thus, there were eight rates of inorganic fertilizer (expt.1: 0; 200 NPK 20:10:10 + 200 K-Nitrate; 300 NPK 20:10:10 + 150 K-Nitrate; 300 NPK 20:10:10 Kg/ha; expt.2: 0, 200 NPK 20:10:10+ 200 Ca-Nitrate, 300 NPK 20:10:10 + 150 Ca-Nitrate and 300 NPK 20:10:10 Kg/ha;) and four colors of polyethylene bags (Blue, Green, Red, Translucent and Bare - as control) replicated three times and laid out in a completely randomized design. Data on weight loss were measured for 7 days. Result showed that percent weight loss increased significantly ($p \leq 0.05$) from day 3 till end of storage for the fertilizer treatment. Colour of polyethylene influenced weight changes significantly ($p \leq 0.05$) throughout the study duration. Application of 200 NPK 20:10:10 plus 200 K-Nitrate or Ca-Nitrate kg/ha had the least weight loss. Similarly, lettuce enclosed in green or blue polyethylene bag had better storage life. Biplot graphic analysis suggested that growing lettuce with 200 NPK 20:10:10 plus 200 K-Nitrate or Ca-Nitrate Kg/ha and stored in green polyethylene had better postharvest storage life.

INTRODUCTION

Lettuce (*Lactuca sativa* L.) is an important leafy vegetable primarily consumed as salad. In addition, lettuce is also consumed for its medicinal advantage particularly for lowering of blood pressure, maintaining healthy heart and heart related issues, due to it terpenoids, vitamins, flavonoids and phenols contents (Noumedem et.al, 2017). Due to these beneficial uses of lettuce, their cultivation is currently gaining attention in Nigeria. However, their cultivation in Nigeria is to a large extent limited to the northern part of Nigeria; this negatively affects utilization of lettuce in the south due to high cost of transportation and storage loss. In addition, the transporting distance between the north and south also negatively affects the quality of lettuce sold in southern Nigeria. Therefore, it is pertinent that lettuce be grown in the southern Nigeria to reduce both economic and health losses associated with its transportation and poor storage. However, the pre-requisite for its growth in this region is less understood. Schofield et.al (2005) in their findings stated that rib discoloration and rot are the major causes of quality loss in postharvest storage of lettuce. This study therefore, focuses on the storage life of lettuce previously grown under different fertilizer treatments and stored in four color-polyethylene bags.

MATERIALS AND METHODS

The postharvest experiment was conducted under room temperature conditions in September 2020 at the Department of Crop Science, University of Nigeria, Nsukka. Four different colors (Blue, Green, Red and Translucent) of polyethylene bags and bare (control) were used for the storage of the lettuce (see Plate 1). Layout was a factorial experiment in completely randomized design and replicated three times. The treatment combinations for growing the lettuce are as shown in the table 1 below:

Table 1: Fertilizers treatment combinations utilized in the field and evaluated in storage experiment

Fertilizer (Kg)	NPK 20:10:10	+ K-Nitrate	NPK 20:10:10	+ Ca-Nitrate
T0	0		0	
T1	200	200	200	200
T2	300	150	300	150
T3	300		300	

Data collection

Storage parameters measured included weight changes and occurrence and severity of rot during the 7-day period in storage across the different polyethylene colors and the control.

Data analysis

All data collected were subjected to analysis of variance (ANOVA) for factorial experiment in CRD and was executed using GENSTAT 7.3E Discovery edition (GENSTAT, 2007). Significant test for treatment means was by Fisher's Least Significant Difference at 5% probability level.

RESULTS

Cumulative weight loss in lettuce (across 7 days) as influenced by fertilizer rates and supplements and the polyethylene colors used for storage are shown in Table 2. Supplementation with either K- or Ca-nitrate significantly influenced weight loss as from the fifth day of storage, K-nitrate had lower weight loss. Among the fertilizer treatments, weight loss was highest when the lettuce was not fertilized. Polyethylene color bags significantly ($p < 0.05$) affected pattern of weight loss. The bare samples (without the modified atmosphere storage environment) had highest weight loss in contrast to the green color that had the lowest.

The biplot (Fig. 1) revealed the combined effects of fertilizer treatment, fertilizer supplement and the polyethylene color pattern of weight changes in storage. It was evident that all the "T" (Bare and laid on the Table) had the highest and most distinct weight loss of lettuce. Most prominent weight loss was the non-fertilized lettuce that was bare, as seen in the figure, which is the T0 (Table and treatment 0), while GK2 (Green 200 NPK 20:10:10 + 200 K-Nitrate kg/ha) had the least postharvest weight loss.

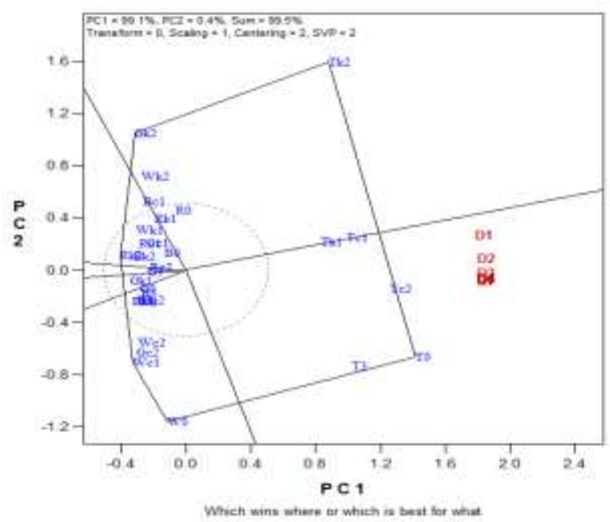

Fig. 1: Biplot showing combined effects of NPK 20:10:10 fertilizer supplemented with K- and Ca- nitrated and stored in four polyethylene colours for seven days.

Plate 1: Experimental layout showing lettuce enclosed in four different polyethylene colours.

Bare	17.27	29.29	39.48	48.44	55.28	59.62	65.62
LSD $_{(0.05)}$	2.158	3.592	3.850	4.602	4.624	4.555	4.507

NS: Non Significant; Wtl: Weight loss; T0,T1,T2,T3: Fertilizer rates in combination with K- and Ca- nitrate as supplements, See Table 1 for interpretation.

DISCUSSION

Loss of weight in vegetables during storage is caused by water exchange between the internal and external atmospheres, the transpiration rate being accelerated by cellular breakdown (Woods, 1990). The K-Nitrate supplement showed lesser storage weight loss as compared to Ca-Nitrate supplement; this is consistent with the known effect of K on regulation of stomata opening in plants. The fertilizer treatment T1 (200kg of NPK 20:10:10 supplemented with either 200kg K-Nitrate or Ca-Nitrate per hectare) exhibited the least postharvest loss compare to other fertilizer rates. Suggesting that increase in fertilizer level decreased post harvest weight loss in this study and also reduces the rate of chlorophyll dissipation and leaf decay. However, from day 5, decay and rot were observed in some of the samples, especially the red, blue and translucent polyethylene bags.

In conclusion, maximum days of storage for lettuce, under a modified atmosphere storage is 5 days in which the level of greenness and crispiness are still acceptable; storing with green polyethylene with perforation at the edges of the bag to allow minimal respiration (exchange oxygen and carbon dioxide) was more preferably.

ABSTRACT

Onion is a seasonal crop with low storability, but due the high demand of its bulbs throughout the year round, it is usually stored in ambient storage conditions until the harvest of next season crop or for longer period to avoid the glut in the market as well as to ensure its year round availability. This study evaluated the effect of elevation on storage conditions and physiological loss of onion bulbs stored in naturally ventilated cribs Medium-sized of Kano-red onion bulbs were stored in three wooden cribs elevated 500mm, 1000mm and 1500mm above ground level for a period of 90 days. The results showed that elevation significantly ($p<0.05$) affected the storage temperature and relative humidity of the cribs as well as the physiological loss factors of the stored the onion bulbs in the cribs. Under storage conditions, temperature and relative humidity were evaluated, while weight loss, sprouting, rotting, rooting and scale-drying were evaluated under physiological loss. The highest and lowest mean temperature and humidity levels of 28.92°C; 72.56% and 27.74°C; 71.90% were observed in the lowest (500mm) and highest (1500mm) elevated cribs, respectively. The lowest mean per cent weight loss of 2.98% and scale-drying loss of 1.9% were observed in the highest elevated cribs, while the highest mean per cent weight loss of 8.57% and scale-drying loss of 6.4% were recorded in the lowest (500mm) elevated cribs. On the other hand, the lowest mean per cent sprouting of 1.7% and rooting of 0.13% were observed in the lowest elevated cribs, while the highest mean per cent sprouting of 6.9% and rooting of 2.02% were obtained in the highest elevated cribs. The lowest mean per cent rotting loss of 0.71% was recorded in the highest (1500mm) elevated cribs, while the highest mean per cent rotting loss of 1.89% was obtained in the lowest (500mm) elevated cribs. It could be deduced that the lowest mean per cent weight loss and scale-drying loss in the highest elevated cribs could be due to the low temperature and relatively high relative humidity levels associated with the cribs, while the lowest sprouting and rooting losses in the lowest elevated cribs could be due to the high mean storage temperature associated with the cribs. The results suggest that for effective storage of Kano-red onion bulbs under natural ventilation, the structures should be raised higher than 500mm above ground level to facilitate enhance bottom ventilation of the structures.

Key words: Onion bulbs, Natural ventilation storage, Ambient conditions, Physiological loss, Bottom elevation

INTRODUCTION

Onion is a semi-perishable bulb vegetable, which like other vegetables is a respiring commodity. However, when harvested and properly cured, it develops dry skin cover which reduces respiratory, extends its shelf-life and minimizes storage losses (Lawande and Tripathi, 2019). Hence, onion bulbs are usually stored in ambient storage conditions until the harvest of next season crop or for longer period to minimize seasonal glut in the market and to ensure availability of the commodity all year round (Dabhi and Patel, 2017). In a developing country like Nigeria, where cold storage facilities are lacking, high-temperature storage technology is predominantly practiced by farmers using traditional techniques at ambient conditions (Fumen, 2016). In Nigeria, the most popular and best storage variety of onion grown is the 'Kano-red' variety which is locally referred to as *Jan-Kano* (Messiaen and Rouamba, 2004; Fumen, 2016). It is mainly produced during the dry season farming, with the cropping duration being between the months of September and April and the peak harvesting period between the months of March and April (Muhammad *et al*., 2011; Jidda and Benjamin, 2016). Within the two-month harvesting period, onion bulb supply is in surplus that the local market cannot absorb, thereby leading to a seasonal glut situation (Ogunesan, 2012). Like most horticultural crops, onion is susceptible to post harvest losses among which weight loss, rotting, sprouting and rooting rank above others (Jolayemi *et al*., 2018). Hence, despite of the ample production of the bulb vegetable and its wide utilization, onion has a very short postharvest shelf-life with a loss of about 40-

50% before reaching the market (Priya *et al*., 2014; Karthik *et al*., 2016).

Although onion is regarded as a semi-perishable crop, post-harvest losses of 10-12%, 8-10% and 30- 40 % due to rotting, sprouting, and physiological weight loss, respectively, occur during storage (Fumen, 2016; Dabhi and Patel, 2017). To extend the period of availability as well as maintaining bulb quality of stored onion, the metabolic breakdown and microbial deterioration of stored bulbs should be objectively minimized (Dabhi and Patel, 2017). In Nigeria, farmers store onion mostly in naturally ventilated storage structures as per their requirements and availability of material, which have no control of temperature and relative humidity. These storage structures which lack adequate ventilation, neither bottom ventilation nor side ventilation often result in increased storage losses of 50% and above (Fumen *et al*., 2017b; ICAR, 2019). Hence, farmers usually sell their onion stocks within the harvest season at a give-away price due to market glut situation or store for a few weeks in the traditional storage structures and suffer losses (Fumen, 2016). Depending on cultivar, cultural practices, pre-harvest and post-harvest treatments, storage losses under traditional storage structures vary between 30 and 50% for short-term and 50 and 90% for long-term storage (Endalew *et al*., 2014; Petropoulos *et al*., 2016; Chávez-Mendoza *et al*., 2016). The naturally ventilated storage structures results in poor aeration which does not adequately remove heat and moisture from the stored onion bulbs, thereby leading to increase in storage temperature, which in turn adversely affects the product storage physiology and pathology, resulting in higher storage losses and decrease in quality (Tripathi and Lawande, 2016; Dabhi and Patel, 2017).

To achieve and maintain a proper high-temperature storage conditions of 25-30°C temperature and 55%-70% relative humidity (Kukanoor, 2005; Haliru *et al*., 2019), external climatic conditions such as temperature, wind velocity and wind direction as well as internal conditions such as layout, construction type, vent positions and product arrangement are considered to enhance proper circulation of fresh air in a storage structure (Ganguly and Ghosh, 2011; Endalew *et al*., 2014). Poor ventilation often adversely affects the quality and quantity of stored onion through increase in water loss and respiration (Dabhi and Patel, 2017). Use of locally made bamboo structures with improved bottom and side ventilation was found to record minimum onion bulb rot and sprouting losses (Yadav and Yadav, 2012). Storage losses of onion bulbs in aerated basket at room temperature were found to be lower than those in poorly ventilated structures with different roofing materials (Imoukhuede and Ale, 2015; Jolayemi *et al*., 2018). Storability of onion bulbs in a storage structure demarcated into three shelves elevated at 1300mm, 900mm and 500mm above ground level showed that the highest elevated shelf recorded the lowest percent weight loss, while the lowest elevated shelf recorded the highest percent weight loss (Falayi and Yusuf, 2014). Minimum onion bulb bruising and rotting have been observed in fully ventilated structures elevated above the ground with adequate bottom and side ventilation than in conventional storage structures without bottom aeration (Soomro *et al*., 2016).

Although Nigeria is among the world's major onion producing countries and the biggest producing country in sub Saharan Africa (Pasternak *et al*., 2013), lack of adequate storage facilities results in losses of 50-76% annually (Denton and Ojeifo, 1990), thereby leading to scarcity and fluctuation in price of the produce annually (Ogunesan, 2012). The objective of this study, therefore, was to determine how bottom ventilation affects physiological activity of onion bulbs in naturally ventilated storage systems.

MATERIALS AND METHODS

This study was carried out at the Department of Agricultural and Bioresources Engineering, School of Engineering and Engineering Technology, Federal University of Technology, Minna, Nigeria, in 2014. Bulk sample of cured bulbs of *Kano-Red* onion variety was obtained from a local market in Minna, Niger state. The *Kano-red* onion variety is characterized by its marked pungent flavour, high dry matter content, firm and tight outer scales, and closed neck which enable it a longer storage period (Messiaen and Rouamba, 2004). The onion bulb sample was cleaned, sorted and graded into small-sized, medium-sized and large–sized grades of diameter >40.0mm, 40.0-60.0mm and <60.0mm, respectively (Messiaen and Rouamba, 2004; Abd-El Rahman and Ebeaid, 2009). The medium-sized grade was selected for the study.

Nine (9) wooden cribs with storage chambers of dimensions 40 × 40 × 40 mm each were used for this study. The cribs were classified into three classes based on the height of the cribs above ground level (Falayi and Yusuf, 2014). Rectangular shaped cribs were covered with brown fibre net and elevated 500mm, 1000mm and

1500mm above ground level (Plates I, II and III). The brown coloured fibre net of 18mm mesh was used as cover for the storage chambers for base floor, side wall and top ceiling, to allow for uniform air circulation and adequate bottom and side ventilation of the cribs (Soomro *et al*., 2016). For uniformity of storage conditions, proximity of experimental units for easy monitoring, protection of the stored onion bulbs against sun and rain intensity and economy of space, the cribs were sheltered under a naturally ventilated thatched shed (Plate IV).

Plate 1: Rectangular mesh cribs elevated 500mm above ground level

Plate II: Rectangular mesh cribs elevated 1000mm above ground level

Plate III: Rectangular mesh cribs elevated 1500mm above ground level

Plate IV: A cross section of naturally ventilated cribs in a thatched shed

Fourteen kilogram (14kg) weight of onion bulbs at 68.9% moisture content (wb) was loaded into each crib for a storage period of 90 days. Using a digital temperature/humidity measuring device, as adopted by Chávez-Mendoza *et al.* (2016), the storage temperature and humidity of each crib were monitored 5 days per week, at the intervals of 9:00am, 1:00pm and 5:00pm, daily. At the intervals of 14days, losses due to decrease in weight, sprouting, rotting, rooting and scale-drying of the stored onion bulbs in each chamber were evaluated to measure the quality of the stored onion. Storage losses due weight loss (Wl), sprouting loss (Sl), rotting loss (Rttl), rooting loss (Rtl) and scale-drying loss (Scdl) were determined using the following equations (Soomro *et al*., 2016; Shankar *et al*., 2017).

Weight loss (Wl%)

$$Wl(\%) = \frac{Wi-Wf}{Wi} \times 100 \quad (1)$$

Where, wi = initial weight of onion bulbs in a chamber before storage interval and wf = weight of onion bulbs in a chamber after a storage interval.

Sprouting loss (Sl%)

$$Sl\ (\%) = \frac{Nsb}{Nib} \times 100 \quad (2)$$

Where, Nsb = number of sprouted bulb at an interval of inspection and Nib = initial number of bulbs in a chamber before the storage interval.

Rotting loss (Rttl%)

$$Rttl(\%) = \frac{Nrttb}{Nib} \times 100 \quad (3)$$

Where, Nrttb = number of rotting bulb at an interval of inspection and Nib = initial number of bulbs in a chamber before the storage interval.

Rooting loss (Rtl%

$$Rtl(\%) = \frac{Nrtb}{Nib} \quad (4)$$

Where, Nrtb = number of rooting bulb at an interval of inspection and Nib = initial number of bulbs in a chamber before the storage interval.

Scale-drying loss (Scdl%)

$$Scdl\ (\%) = \frac{Nsd}{Nsi} \times 100 \quad (5)$$

Where, Nsd = mean number of dry scales from 3 randomly selected onion bulbs a storage interval and Nsi = mean number of fleshy scales from 3 transversely sliced onion bulbs before storage interval.

Statistical Analysis

Using SPSS 11.5 for Windows, arithmetic mean, standard deviation and coefficient of variance were the statistical tools used in computing and comparing the data generated. Student-Newman-Keul's (SNK) test, was used to determine the effect of elevation on the storage conditions of the ventilated cribs and the physiological loss parameters of stored onion at 5% level of probability (Chukwu and Sunmonu, 2010).

RESULTS AND DISCUSSION

The results of the effect of elevation on mean temperature and relative humidity of naturally ventilated cribs and the mean physiological losses of onion stored in the cribs for the 90-day storage experiment are presented in Table1 and Figures 1-5, respectively.

Effect of Elevation on Temperature and Humidity of Naturally Ventilated Cribs

The result of the effect of elevation on the inside temperature and relative humidity of naturally ventilated rectangular cribs show that both temperature and air relative humidity were significantly ($p < 0.05$) affected by elevation throughout the 90-day storage experiment.

Table 1: Effect of elevation on temperature in naturally ventilated cribs at different storage periods

Elevation (mm)	Mean temperature(°C) and relative humidity (%)							
	July, 2014		August,2014		September, 2014		Total mean	
	(°C)	(%RH)	(°C)	(%RH)	(°C)	(%RH)	(°C)	(%RH)
500	29.20a	71.97a	28.51a	73.86a	29.05a	71.86a	28.92a	72.56a
1000	28.79b	71.70b	27.87b	73.78b	28.21b	71.79b	28.29b	72.42b
1500	28,46c	71.68c	27.30c	72.76c	27.47c	71.26c	27.74c	71.90c
SE±	0.012	0.049	0.011	0.034	0.009	0.028	0.011	0.037

*Mean values with the same letter in a column are not signicantly different at 5% level of probability using Student-Newman-Keul's (SNK) test.

Storage temperature was found to be highest in the lowest elevated (500mm) cribs with a mean temperature of 28.92°C and lowest in the highest elevated (1500mm) cribs with a mean temperature of 27.74°C. During the 90-day storage experiment, storage temperature in the lowest elevated cribs was highest (29.20°C) in the month of July and lowest (28.51°C) in the month of August. While in cribs elevated 1000mm and 1500mm above ground level, storage temperature was highest (28.79°C; 28.46°C) in July and lowest (27.87°C; 27.30°C) in August, respectively. In September, the temperature levels dropped to 28.21oC and 27.47°C, respectively. The results show that there was fluctuation in the storage temperature of the cribs during the storage period. This suggests that the higher a storage structure is elevated above ground level, the lower the storage temperature of the structure, agreeing with Thompson (2002) and Kitinoja and Kader (2003) that increase in altitude lowers air temperature of the affected area and that at every 1km rise in altitude, temperature drops by 10°C. Ganguly and Ghosh (2011) stressed that storage structures elevated 1500mm above ground level have colder outside air flow into them to replace the inside warm air, thereby keeping the structures cooled.

The effect of elevation on relative humidity of the naturally ventilated cribs was also significant ($P<0.05$) as the highest air humidity levels of 71.97%, 73.86% and 71.86% were found in the lowest elevated (500mm) cribs, while the lowest air relative humidity levels of 71.68%, 72.76% and 71.26% were observed in the highest elevated (1500mm) cribs. The effect however fluctuated during the study period as the air relative humidity levels were relatively low (71.97%, 71.70% and 71.68%) in the month of July, high (73.86%, 73.78% and 72.76%) in the month of August and low (71.86%, 71.79% and 71.26%) in the month of September. The result suggests that elevating a storage structure high above ground level has a significant cooling effect on the storage conditions of the storage products, with moderate air relative humidity. This corroborates the report of Cantwell and Kasmire (2002) that elevating storerooms 500mm above ground level prevents them from soil moisture effect and dampness.

Effect Elevation on Physiological Losses of Stored Onion in NaturallyVentilated Cribs

The results of effect of elevation of naturally ventilated cribs on physiological losses of stored onion bulbs are presented in Figures 1-5. The results show that elevation significantly ($p < 0.05$) influenced physiological losses in the stored onion bulbs. The result shows that the lowest mean per cent weight loss of 2.98% was observed in the highest elevated (1500mm) cribs, while the highest mean per cent weight loss of 8.57% was recorded in lowest elevated (500mm) cribs. This suggests that the lowest elevated (500mm) cribs with higher temperature levels recorded the higher per cent weight loss while the highest elevated (1500mm) cribs with lower temperature levels recorded the lower per cent weight loss. The result is in conformity with the report of Watkins and Nock (2012) and Sohany *et al*. (2016) that moisture loss from onion bulb is greater at room temperature of more than 27˚C.

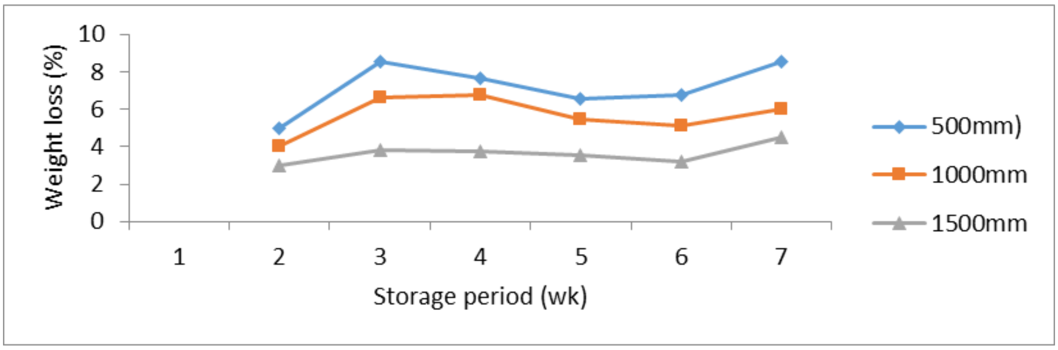

Figure 1: Effect of elevation on mean per cent weight loss

With reference to Table 1, the highest temperature levels were observed in the lowest elevated (500mm) cribs. The high mean per cent weight loss in these cribs could be attributed to the high temperature levels associated with the cribs (Sohany *et al*., 2016). This could also be attributed to the high transpiration and respiration due to the comparatively high temperature and optimum relative humidity in the cribs (Endalew *et al*., 2014). Storage of onion in a storage structure with adequate bottom and side aeration can result in high reduction in physiological loss in weight (Mangaraj *et al*., 2017).

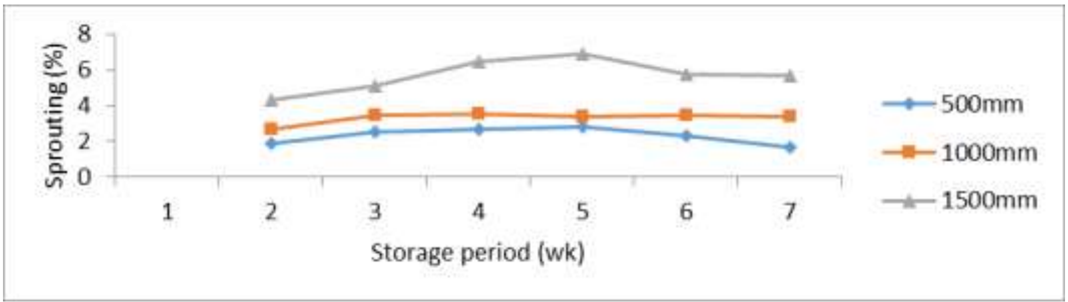

Figure 2: Effect of elevation on mean per cent sprouting loss

Figure 2 shows that the lowest elevated (500mm) cribs maintained the lowest mean percent sprouting of 1.7%, while the highest elevated (1500mm) cribs maintained the highest mean per cent sprouting of 6.9%. The result depicts that storage of onion in high temperature stores suppresses bulb sprouting. Reference to Table1, the lowest sprouting loss in the lowest elevated cribs could be attributed to the high mean storage temperature levels in the cribs, while the highest mean per cent sprouting in the highest elevated cribs could be as a result of the moderate temperature levels associated with the cribs. This conforms to the reports by Singh (2012), Sohany *et al*. (2016) and Fumen *et al*.(2017a) that the combination of moderate temperature (9-18°C) and high relative humidity (> 75%) favours rapid bulb sprouting, while the combination of high temperature (> 32°C) and moderate relative humidity (<60%) suppresses bulb, thereby extending the dormancy period of stored onion bulbs.

Figure 3 shows that the highest elevated (1500mm) cribs maintained the lowest mean per cent rotting loss of 0.71%, while the lowest elevated (500mm) cribs recorded the highest mean per cent rotting loss of 1.89%. The results suggest that onion bulb rotting is higher in hot and humid storage conditions, thereby conforming to the report that hot and humid storage conditions are susceptible to the growth of black mold (*Aspergillus niger*), bacterial soft rot (*Pseudomonas gladioli*) and other storage diseases which cause bulb rotting in stored onion (Sohany *et al*., 2016; Jidda and Benjamin, 2016).

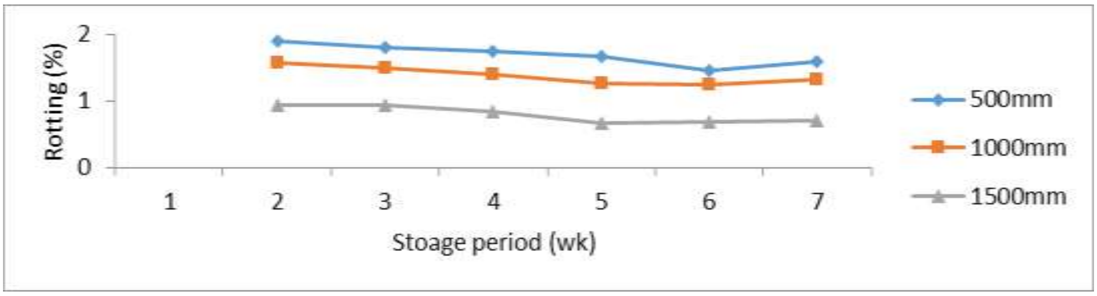

Figure 3: Effect of elevation on mean per cent rotting loss

In Table 1 above, the highest elevated (1500mm) cribs maintained moderate temperature and humidity levels, while the lowest elevated (500mm) cribs maintained the highest temperature and humidity levels. Thus, the lowest mean per cent rotting loss of 0.71% in the highest elevated cribs could be attributed to the moderate temperature levels associated with the cribs. The high mean percent bulb rotting loss in the lowest elevated cribs could be attributed to the high temperature and high humidity levels associated with the cribs (Singh, 2012; Fumen *et al*., 2017a).

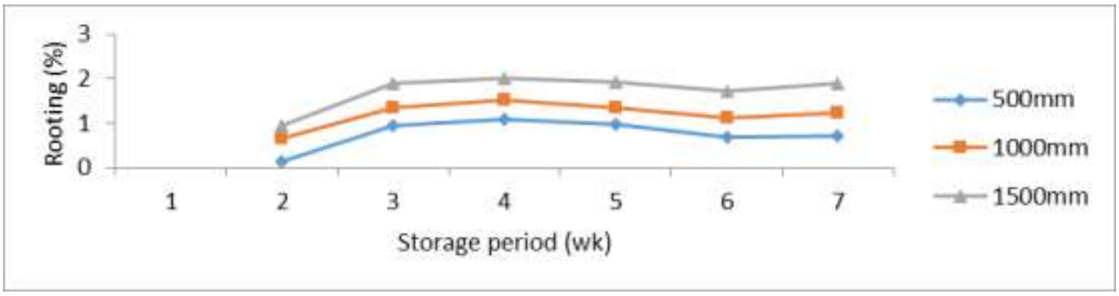

Figure 4: Effect of elevation on mean per cent rooting loss

In Figure 4, the lowest elevated cribs recorded the lowest mean per cent rooting loss of 0.13%, while the highest mean per cent rooting loss of 2.02% was obtained in the highest elevated cribs. Reference to Table1, the result suggests that the lowest mean percent rooting loss recorded in the lowest elevated cribs could be attributed to the high temperature levels associated with the cribs, while the highest percent rooting loss in the highest elevated cribs could be attributed to the intermediate temperature and high relative humidity levels associated with the cribs. This result conforms to the report that a combination of moderate (10-20°C) temperatures and high (> 75%) relative humidity favours rooting loss in stored onion bulbs (CIGR, 1999).

In Figure 5, the lowest mean per cent scale-drying of 1.9% was recorded in the highest elevated cribs, while the highest mean per cent scale-drying loss of 6.4% was obtained in the lowest elevated cribs. With reference to Table1, the highest temperature levels were recorded in the lowest elevated cribs, while the lowest temperature levels were maintained in the highest elevated cribs. The result suggests that the lowest mean per cent scale-drying loss in the highest elevated cribs could be attributed to the low temperature and humidity levels associated with the cribs, while the highest mean per cent scale-drying loss in the lowest elevated cribs could be attributed to the high temperature levels associated with the cribs. The result conforms to the report by Fustos (1997) that scale-drying in stored onion is minimized rapidly at low temperature and moderate (<60%) air relative humidity.

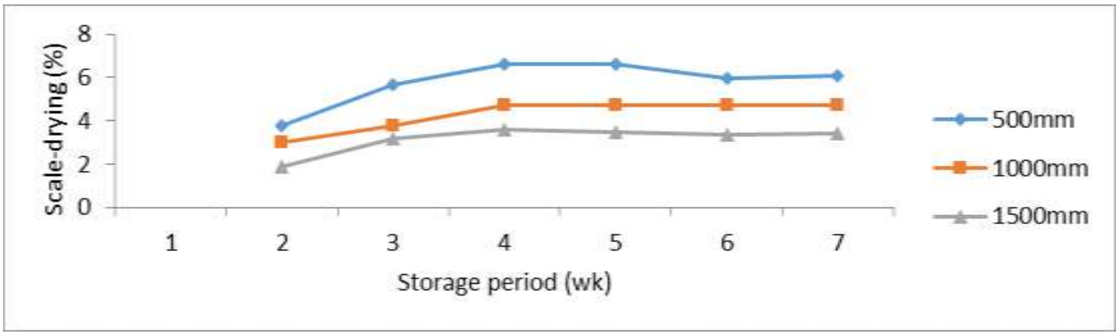

Figure 5: Effect of elevation on mean per cent scale-drying loss

CONCLUSIONS

Effect of elevation of naturally ventilated cribs on storage conditions and physiological loss in stored onion bulbs was evaluated. Medium-sized of *Kano-red* onion bulbs were stored in three wooden cribs elevated 500mm, 1000mm and 1500mm above ground level for a period of 90 days. Bottom elevation significantly ($p<0.05$) influenced the storage conditions of the cribs as well as the physiological loss in the stored onion bulbs. The highest mean storage temperature and relative humidity were observed in the lowest (500mm) and highest (1500mm) elevated cribs, while the lowest mean temperature and relative humidity were both observed in the highest elevated (1500mm) crib. The mean per cent weight loss of the stored onion was lowest (2.98%) in the highest elevated (1500mm) crib and highest (8.57%) in lowest elevated (500mm) crib. The lowest mean percent bulb sprouting of 1.7% was recorded in the lowest elevated (500mm) cribs, while the highest (6.9%) was obtained in the highest elevated (1500mm) crib. While the lowest mean per cent rotting loss of 0.71% was observed in the highest elevated (1500mm) crib, the lowest elevated (500mm) crib recorded the highest mean per cent rotting loss of 1.89%. The mean per cent rooting loss was lowest (0.13%) in the lowest elevated crib and highest (2.02%) in the highest elevated crib. The lowest mean per cent scale-drying of 1.9% was recorded in the highest elevated cribs and the highest (6.4%) in the lowest elevated crib. The study suggests that raising storage structures higher than 500mm above ground level reduces the storage temperature and increases the relative humidity of the structure, thereby minimizing weight loss, bulb rotting and scale-drying in stored onion.

ANTIOXIDATIVE AND ANTIFUNGAL EFFECTS OF COFFEE HUSK PASTE ON THE SHELF LIFE QUALITY OF SMOKED TILAPIA (*SAROTERODON GALILEA*)

Adebowale, B.A., Orimoloye, P.O., Mustapha, K. and Olusola, M.

Value Addition Department, Cocoa Research Institute of Nigeria, P.M.B. 5244, Ibadan

ABSTRACT

Antioxidative and antifungal effects of different concentrations of coffee husk paste were tested on smoked tilapia (saroterodon galilea) stored for 4 weeks at ambient temperature of approximately 28^{0}C. Five bathes of eviscerated, brined fish fillets were each coated with 0%(A), 1.0%(B), 2.0%(C), 3.0%(D), and 4.0%(E) coffee husk paste and smoked in a gas oven. The cooled stored fillets were then examined and analysed periodically after every week of storage. Gradual decrease in the values of the two antioxidative indicators: thiobabituric acid (TBA) and peroxide value (PV) as the level of coffee paste increased, shows that rancidity of fish tissue is been retarded by the coated coffee husk paste. Antioxidative activity of coffee paste was in this order: B<C<D<E. Higher and steady increase in the rate of rancidity of fillet than all other treatments were noticed in the control (0%) as storage days increased. This was indicated by the TBA values. At the end of the fourth week, lowest value of TBA (0.41) was obtained in treatment E (5%). Although this was higher than the value obtained after the second week. Similar trend was also observed for the peroxide values of the same treatment. This might be due to slight increase in the moisture content of the samples at the stage of storage. Colony count of fungal growth on fish fillets was lowest (4.10 x 10^4) on treatment E as against A (0%) and other lower concentrations at day 21. At the end of the study, least fungal growth (6.02 x 10^4) was recorded on E, thus indicating highest antifungal activity of coffee husk paste on fish fillets. Results of sensory evaluation however show least preference for treatment E. This was as a result of poor appearance (2.46) and flavor (3.18), although lowest value (3.14) was recorded for the degree of rancidity. Thus, coffee husk paste exhibited antioxidative and antifungal actions on the smoked fish and could be used to extend the shelflife of smoked fish.

Key words: Rancidity, Shelflife, Ambient temperature, Fillet, *Saroterodon galilea*

INTRODUCTION

Protein consumption per head in any developing or underdeveloped countries in concernedly low when compared to other developing countries of the world (Maeve *et al*., 2017). Minimum daily protein consumption per head should not be below 0.8 grams of protein per kilogram of body weight (WHO/ FAO/ UNU (2007). Animal protein is and still remain the better source of protein in the class of food (https://www.webmd.com). Sources of animal protein are many depending on the level; of development of any countries livestock sector. However, fish as a source of animal protein remains an excellent source due to some reasons. Fish has been reported to contain very high level of sulphur containing amino acids such as: cysteine, methionine and lysine. Such amino acids as mentioned above a grossly lacking in legumes and most cereal based diets (https://www.healthline.). In Nigeria, fish still remains the cheapest source of animal protein when compare to other sources of animal protein (particularly meat).

Fish has two major sources of supply: the capture and culture fishery. Fish from either of these sources easily spoil as a result of oxidative rancidity (particularly fat fish) if not properly cared for during processing and preservation. This is because fish is an easily and highly perishable commodity most especially at temperate regions of the world (Nigeria inclusive). Fish protein undergo spontaneous rancidity within 24 hours' postmortem (Ames *et al.,* 1993). The occurrence poses a major setback for the artisanal sector of most underdeveloped countries of the world, as negligible proportion of the catch is finally gets to the market in good condition. This undoubtedly reduces their average daily income realizable from their business.

Coffee is one of the most popular beverages, is consumed by millions of people every day. This is as a result of the concentration of important polyphenolic compounds like cinnamic acids, benzoic acids, flavonoids, proanthocyanidins, stilbenes and lignin. Most of these compounds possess antioxidatative properties (Rice *et.al,* 1996). Studies have also shown that coffee pulp obtained from deshelling (dry pulping) the ripe coffee beans equally contain significant proportion of polyphenolic compounds. However, some of these compounds of have been detected to be antinutritional in nature. This thus deters its utilization as animal feedstuff. Coffee byproducts proportion is about 50% (dry matter) of the world coffee production, and about 2.8 million tonnes of this pulp was reportedly produced between 1989-1990 (Perraud-Gaime, 1995). Despite the high global production of this husk, Hamzat (2011) reported that coffee pulp and husk usually constitute a major pollutant of lakes and rivers around the coffee processing sites (farms and industries). Hence, coffee pulp is hitherto facing serious disposal problem. Coffee husks and pulp, which comprises nearly 45% of the cherry, are one of the main by-products of coffee agro-industry and might be a valuable material for several purposes, including extraction of caffeine and polyphenols. Coffee pulp contains 23.3 % (DM) in the following proportions: 3.4% fiber, 2.1 % protein, 1.5 % ash, non-protein and organic components like tannins, sugars, caffeine, chlorogenic acid and caffeic acid. Additional phenolic compounds such as flavan-3-ols (monomer and proanthocyanidins), hydroxynamic acid (caffeolquinic acid, caffeolquinic acid derivates and p- c oumaroylquinic acid), flavonols and anthocyanidins were present in the pulp. Tannins and caffeine extracted from coffee were found to inhibit *Staphylococcus aureus*, *Vibrio parahaemolyticus, V. cholerae,* and *Salmonella*.

Synthetic antioxidants, widely known and have being in use for long is today being discouraged. This is as a result of the health implication of synthetic products. This thus necessitates the need to search for alternative preservative materials which could effectively tackle the problem of spoilage of seafood and frozen products which are highly perishable. In seafood like fish, oxidative rancidity and microbial proliferation are the two major sources of spoilage.

MATERIALS AND METHODS

Fish sample

Twenty-five kilogrammes of table size fresh tilapia (*saroterodon galilea*) was purchased from a local artisanal fishermen Odo-Ona village, Ibadan. and brought to the experimental site where it was immediately eviscerated by removing the intestine and gills through cutting of the abdominal region of each fish. They were thoroughly washed in clean water. Fish fillets were then dipped in 15% sodium chloride (brine) solution for 3 minutes after which it was drained. The processed fish were divided into five batches into sterilized clean stainless container and labeled A, B, C, D and E.

Coffee hush paste

Dry processed coffee husk sample was collected from Value Added Research Department of Cocoa Research institute of Nigeria, Ibadan. Five kilogramme of the dried sample of the husk were thoroughly grinded using local pepper milling machine and then milled into finer particles using local grinding stone to form a powder. 0 to 5% concentration of coffee husk paste were made by adding 1litre of water each into 100, 200, 300 and 400gms of powder coffee husk in different containers. This solution is then mixed together thoroughly to form paste. Each of the pastes were then pore on each of the five batches of fish in the containers with the exception of sample A (control). The paste is now mixed with the fishes to cover all the entire surfaces of the fish.

Smoking of fish

A gas oven with a regulated temperature of 60^0C. Smoking was done for about two hours with four turning times.

Storage and sampling of fish sample

Each bathes of the fish were allowed to cool down so as to avoid steam effect. Each bathes (A, B, C, D and E) were later packaged into air-tight black polythene bags and stored at ambient temperature of about 30^0C for four weeks. At the end of the fourth week, samples were then subjected to visual observation for fungal growth and sensory evaluation. Chemical and microbiological evaluations were later carried out on the samples in the laboratory.

Chemical analysis

Protein, lipid, moisture content, Thiobarbituric acid (TBA) and the peroxide value of samples were determined.

Microbiological analysis

Visual examination of fish samples was done weekly and data from each batch were taken accordingly. Mould counts of sample were determined.

Sensory evaluation

Four (4) member panel comprising of well experienced taste panelist, was composed to examine the samples. To facilitate unbiased examination, all samples were rinsed in clean water and covered with aluminum foil and then heated for about 25 minutes in gas oven at a temperature of 70^0 C. Each batch were later presented one after the other in a regular order before each of the taste panelists after cooling down of samples to room temperature. Panel members were to score each sample for: appearance, saltiness, juiciness, flavor, rancidity (off flavour) and the general acceptability of samples, base on a 5-point hedonic scale.

Statistical analysis

Analysis of variance was used to analyze the data obtained. Duncan Multiple range test was employed in determining the differences in means.

RESULTS

The effects of different concentrations of coffee husk paste on the examined qualities of the smoked tilapia samples are shown on table 1- 6. Different levels of coffee husk past have imparted certain degrees of antioxidative and antifungal effects on the smoked fish fillets. Moisture contents of all the smoked samples decreased progressively as days of storage increases, until after the fourteenth day. Thus rise in the moisture content was however absent in treatment E. Percentage water activity of the smoked fish samples also followed the same trend as in the moisture content. Highest rate (0.12) of reduction in the water activity was obtained in the sample with the highest coffee paste concentration.

Levels of thiobabituric acid (TBA) increased in all the fish samples, with highest value (0.89) in A (control) and least (0.41) in E (4%). The difference between the initial TBA values was equally highest (0.48) in A and least (0.03) in E, in this order A> B >C >D >E. Initial peroxide values (rancidity indicator), have trends closely similar to that of the TBA. Initial peroxide value was lowest in treatment D (3%), while that of B (10.9) was the highest. Trend of these values changed after the third week of storage. Peroxide values which increased across table till the end of the third week gradually decreased till the end of the storage period. At the end, highest value (8.0) of peroxide value was found in A as against the least (4.2) value in E. Final values obtained in all the coffee husk treated samples have no regular trend. All treated samples were however lower than that of the control. Results of the physical examination of the treated fish shows highest (14.6×10^4) in the control and least value (6.02×10^4) of colony count was found in E. Assessment of samples by taste panelists (Table 6) shows least (2.46) value for appearance in E. Best appearance (5.62) was recorded for treatment C. For rancidity, sample A had the highest (4.66) value and the least (3.14) activity was found in E. Treatment C had the best (5.44 and 6.42) values respectively for flavor and general acceptability. Treatment A scored least for flavour while had least value for general acceptability.

DISCUSSIONS

Poverty and disease incidence are closely related and hence management of either of them should be done together. Fish is said to be one of the food of the poor people. This is because it is relatively cheaper than meat. This consequently makes cheaper protein sources like fish much more relevant in this global pandemic period. One of the proffered solutions to lowering the spread of corona virus is the maintenance of good hygiene among the citizen of any country. By avoiding or preventing the accumulation of all environmental pollutants, such as sewage effluents, industrial wastes as well as agricultural byproducts, good hygiene would be maintained. Hence an environment voids of diseases which could predispose people to health related problems like corona could be provided. Coffee farmers and fish processors could contribute to the alleviation of infections like corona. Lockdown, which is one of the global measures to reduce the spread of covid 19, has negative effects on almost every aspect of human life, most especially the industrial and agricultural sector of the economy. The aftermath of which is mass retrenchment of workers and considerable cutdown in the income per head of citizen. If smoke fish shelf life could be extended simply by the application of coffee husk as natural preservative, consumption of contaminated fish products by people would be prevented. Coffee farmers in turn will have their income raised. In conclusion, increase in coffee farming, which will indirectly increase coffee husk production and utilization may be a right step in the right direction.

ABSTRACT

The conversion of agro-residues into various value-added products is attracting global attention. Cashew (Anacardium occidentale) apple juice is an interesting low-cost substrate for microbial production of lactic acid. The juice is highly rich in reducing sugars (fructose and glucose), vitamins, minerals and some amino acids. In Nigeria, the goal of cashew tree cultivation is mostly directed towards nut production. This exposes the cashew apple to natural decomposition and wastage. Although, research works on utilization of cashew apple juice as a substrate for lactic acid production abound, its potential as an alternative source of income to the Nigeria government is still sketchy. This paper provided information on the procedural approach for lactic acid production vis-à-vis its prospects in income generation to the Nigerian government.

Key words: Cashew, lactic acid, reducing sugars, vitamins, amino acids

INTRODUCTION

Cashew (*Anacardium occidentale*) is an important evergreen perennial tree plant belonging to the family Anacardiaceae. It is cultivated in many African countries such as Nigeria, Tanzania, Ivory Coast, Mozambique, Benin and the Tropical countries such as Vietnam and India (Daramola, 2013). Cashew apple is a pseudo fruit of the cashew tree to which the cashew nut is attached. Cashew apple juice contains reducing sugars such as glucose, fructose and sucrose. It is also a very good source of vitamins, amino acids and minerals. The goal of the cashew tree cultivation is directed towards nut production. The nuts represent only 10% of the total fruit weight, and large amounts of cashew apples are lost in the field after nut removal (Rabelo *et al*., 2009). The use of cashew apple as a source of high value-added products may represent an important source of national income (Azevedo and Rodrigues, 2000).

Lactic acid (2-hydroxypropanoic acid), $CH_3CHOHCOOH$, was first discovered in sour milk by the Swedish chemist Scheele in 1780 (Datta and Henry, 2006). It is the most globally synthesized hydroxycarboxylic acid. Lactic acid has a wide documented history of use in the food, pharmaceutical, health and textile industries. It is widely used in the production of sweets, pickled foods and as a raw material in the manufacture of important emulsifiers for the baking industry. Lactic acid also functions as an important metabolite in most living organisms, from anaerobic prokaryotes to humans. Due to its inherent hydroxyl and carboxyl groups, it can be easily converted into useful chemicals such as pyruvic acid, acrylic acid, 1,2-propanediol, and lactate ester (Fan *et al*., 2009). Over the last few years, the demand for lactic acid has greatly increased due to its applicability in the production of biodegradable and biocompatible polymer, polylactic acid (PLA) (Abdel-Rahman *et al*., 2013). Lactic acid is produced by both prokaryotic and eukaryotic organisms. It is the simplest hydroxyl carboxylic acid with an asymmetrical carbon atom that confers optical activity. Lactic acid is found naturally in two optical forms, D-(-) and L-(+)-lactic acids. L-lactic acid is the preferred isomer in food and pharmaceutical industries, since elevated levels of the D-isomer are harmful to humans (Hofvendah and Hahn–Hägerdal, 2000; Bouguettoucha *et al*., 2009).

In relation to the foregoing, many studies have been carried out in order to explore the cashew apple juice as a cheaper source of carbon in fermentation processes for the production of bio-products such as lactic acid (Honorato *et al*., 2007), biosurfactant (Rocha *et al*., 2006) and oligosaccharide (Rabelo *et al*.,2009). Although, there are reviews on lactic acid production through cashew apple juice utilization as a substrate, its potential as a reliable source of income to the Nigerian government is yet to be considered. Hence, this paper attempts to provide information on the procedural approach for lactic acid production vis-à-vis its prospects in income generation to the Nigerian government.

Production of Lactic Acid

Lactic acid can be produced by chemical synthesis or microbial fermentation. However, the latter has some desirous advantages over the former such as the use of cheap raw materials like molasses, starchy waste, cellulosic and other carbohydrate rich materials (Vishnu *et al.,*2000). Another significant advantage is the production of a pure form of lactic acid, whereas, chemical synthesis only provides a racemic mixture of D- and L-lactic acids (Randhawa *et al*.,2012).

Chemical Synthesis of Lactic Acid

The stepwise procedure for chemical synthesis of lactic acid is based on lactonitrile. Initially, hydrogen cyanide is added to acetaldehyde in the presence of a base to make lactonitrile. The reaction occurs optimally at high atmospheric pressures in liquid phase. The crude lactonitrile is separated from the reaction medium and then purified by distillation. The lactonitrile is hydrolyzed to lactic acid using either concentrated sulphuric acid or hydrochloric acid. Apart from the lactic acid, ammonium salt is also produced alongside. Through esterificaton, the lactic acid combines with methanol to yield methyl lactate. The methyl lactate is then hydrolyzed by water in the presence of acid catalyst to produce methanol and lactic acid (Boontawan *et al*., 2011).

Microbial Fermentation

The fermentation process is characterized by a microbial degradation of carbohydrate into metabolites such as lactic acid, citric acid and ethanol (Yasmine, 2002). The carbohydrate material has to be hydrolyzed into fermentable simple sugars via a process that breaks down the alpha-glycosidic bonds. Alpha-amylase (EC3.2.1.1), Beta-amylase (3.2.1.2), and glucoamylase (EC 3.2.1.3) are well known amylolytic enzymes that catalyze the hydrolysis of alpha-glycosidic bonds in starch and other related saccharides (Ying *et al*.,2014). The efficiency of lactic acid fermentation activities is determined by the microorganism used, substrate, and operational conditions. Well-known fermentation approaches that are employed in lactic acid production include batch, fed-batch and continuous batch fermentations (Hofvendahl *et al*., 2000).

Application of Lactic Acid

In the pharmaceutical industry, lactic acid is used as an electrolyte in many parenteral or intravenous solutions that are prepared to replenish the bodily fluids. It is also used in large number of mineral preparations which includes tablets, prostheses, controlled drug delivery systems and surgical sutures (Wee *et al*., 2006). In the food industry, lactic acid is used as an acidulant due to its mild and palatable acidic taste and as preservative and pH regulator. As a result of its bactericidal activity, it is used as an inhibitor against bacteria growth in food processing. Lactic acid is also very effective in preserving and extending the shelf life of dairy products (Wee *et al*.,2006).

Lactic acid is considered an indispensable material in the chemical industry as a result of its desirable properties. It contains two reactive functional groups, a carboxylic group and a hydroxyl group. It functions as a descaling agent, neutralizer, chiral intermediate, cleaning agent and metal complexing agent. Lactic acid also finds applicability in the cosmetic industry where it is used as a moisturizer and skin brightening agent. The moisturizing effect is attributable to lactate's water-retaining capacity, and the skin-lightening action is caused by tyrosinase formation inhibition (Vijayakumar *et al*.,2008). Lactic acid is currently used as a feedstock monomer in the polymer industry for the production of polylactic acid (PLA). PLA, a biodegradable polymer, has numerous applications in activities such as food packaging, mulch film, trash bags and protective clothing (Vink *et al*., 2010).

Economic Benefits of Lactic Acid Production from Cahew in Nigeria

Agricultural development and the production of value-added products from farm residues are powerful tools to boost the economy of a nation, particularly a developing country like Nigeria. The issue of cashew apple losses on farm is of an immense importance in the efforts to propose an alternative source of income to the Nigerian government. After removing the cashew nut, the cashew apples are thrown away or dumped, where they undergo natural decomposition in the soil. This represents a waste of resources incurred during the different phases of cashew propagation and harvesting.

The wide application of lactic acid in various industrial processes corresponds to its higher demand. It is a high value-added product that has been gaining market share with each year (Albuquerque *et al*., 2015). The global consumption of lactic acid has been roughly estimated as 130,000-150,000 metric tons per year (Wee *et al*., 2006). The three largest consumer markets in the world are the United States, followed by China and Western Europe (Komesu *et al*., 2017). As stated here, Nigeria can improve its economy by taking advantage of the large global markets available to lactic acid production.

CONCLUSION

The use of cashew apple as an agro-source for lactic acid production would not only boost the Nigerian economy but also indirectly provide a cost-

ISSN: 2814-0508

effective protocol to manage environmental pollution associated with cashew farming. At the same time, the rate of unemployment that has maintained a rising trend for several years in Nigeria would be significantly reduced.

ABSTRACT

Sweetpotato is an underutilized crop with a high potential to improve food security and nutrition, especially through harnessing sweetpotato accession with high vitamin content and dry matter which will help in filling gap of nutrition and food in security. This research was developed in order to determine the organoleptic properties of selected accession of sweetpotato. The accessions were purchased at the point of harvest from Osun State University Teaching and Research Farm; University of Ibadan Teaching and Research Farm and from Local Farmers in Offa Kwara State. The accessions were washed, peeled, steamed and presented to 50 trained panelists in the laboratory of the Department of Agronomy, College of Agriculture, Osun State University, Ejigbo to determine the organoleptic properties (taste, flavor, texture, appearance, colour of peel and flesh and overall acceptability. Data collected were subjected to analysis of variance at 5% probability. For the organoleptic evaluation Offa accession was extremely liked due to the appearance, colour and taste among other qualities.

Key words; sweetpotato accessions, local farmers, organoleptic, offa accession

INTRODUCTION

Sweetpotato (*Ipomoea batatas* L.) is an important root crop grown in more than 100 countries worldwide (Osiru *et al*., 2009). In sub-Saharan Africa (SSA), it is cultivated in an area of about 3.22 million hectares with an annual production of 14.65 million tonnes which is about 12% of the world total production (FAOSTAT, 2015). Sweetpotato is grown for food, feed and income generation in many countries in Sub Saharan Africa (Low, *et al*., 2009). It is an important food security crop, often crucial during famine due to its excellent drought tolerance and rapid production of storage roots (Mukhopadhyay *et al*., 2011). It is a crucial crop in rural and marginalized communities including many HIV affected and women-headed households in eastern and central Africa (Johanson and Ives, 2001). It has supported more people per unit area than any other crop (Okada *et al*., 2002). In addition to serving as an important complementary food crop, It supplements household income through formal and informal trading at both rural and urban markets, thereby contributing to the alleviation of widespread food shortages and poverty for the majority of rural communities who are dependent on this crop (Mwanga and Ssemakula, 2011). Sweetpotato is a crop plant whose large, starchy, sweet-tasting storage roots are an important root vegetable (Woolfe. 1992). In 2008, Nigeria ranked second in sweetpotato production in Africa, with an annual production output of 2.6 million metric tonnes. While in global sweetpotato production, Nigeria was ranked third (FAO, 2008). These figures have changed in the last decade. Currently, Nigeria is the first largest producer of sweetpotato in Africa with 3.46 million metric tonnes annually (Udemezue, 2019).

MATERIALS AND METHODS

The experiment was conducted at the Laboratory of the Department of Agronomy, Osun State University Teaching and Research farm, Ejigbo Campus, Osun State Nigeria which lies between Longitude 4, 18°13.76"E and Latitude 7, 52°28.37"N during rainy season. Twenty-six (26) accessions of sweetpotato, collected from the University of Ibadan, Oyo State; local farmers in Offa, Kwara State and Teaching and Research Farm Osun State University, Ejigbo, were evaluated for the research (Table 1). The experimental materials were laid out in a Complete Randomized Design (CRD) with five replicates.

The sensory evaluation was carried on the taste, texture, appearance, colour of peel and flesh, flavour and overall acceptance of 26 accessions of sweetpotato roots. Mature tuberous root of each variety were washed and cooked for 15minutes. Each bag containing the sweetpotato roots were labeled and immersed in a pot of boiling water for 15 minutes. A sample of each accession was allowed to cool down and served among a taste panel for rating. The taste panel consisted of 50 people, and each person tasted a set of coded samples. After each tasting, the panelists rinsed their mouths thoroughly with clean water. Each consumers' rate for taste, texture, flavour and overall acceptability of the boiled sweetpotato tuberous roots was noted.

Organoleptic Evaluation

Fifty (50) randomly selected panelists drawn from Osun State University were used. Panelists who are familiar with the sensory properties of boiled sweetpotato roots assessed the prepared boiled sweetpotato for colour of peel and root, taste, texture, and flavor, overall acceptability, and the degree of likeness, using a 4-point Hedonic scale and 7-point Hedonic scale, Where:

1 = Very soft (texture); Poor (taste and flavor); Dislike very much (Overall acceptability).

2 = Soft (texture); Fair (taste and flavor); Dislike extremely (Overall acceptability)

3 = Hard (texture); Good (taste and flavor); Dislike moderately (Overall acceptability).

4 =Very hard (texture); Excellent (taste and flavor); Neither like or dislike (Overall acceptability).

5 = Like moderately (Overall acceptability).

6 = Like very much (Overall acceptability).

7 = Like extremely (Overall acceptability).

Statistical Analysis

Descriptive analysis was adopted, and data collected were subjected to Analysis of Variance at 5% probability.

Table 1. Accessions of Sweetpotato, Skin Colour and Flesh Colour

S/N	Sweet potato Accessions	Skin Color	Flesh Color	S/N	Sweet potato Accessions	Skin Color	Flesh Color
1	Bodija	Cream	Cream	**14**	Usman	Cream	Cream
2	Ladele	Cream	Cream	**15**	Offa 1	Cream	Cream
3	Omini	Dark Purple	Cream	**16**	Molete	Cream	Cream

13	Sango	Cream	Cream	**26**	BD	Cream	Cream

RESULTS AND DISCUSSION

Table 2 revealed that 70% of the respondents were between the ages of 15-30. The mean age of the respondent was 24.5 which implies that majority of the respondents were in the middle age. In addition, the distribution of the respondents by sex showed that majority (59.40%) were female compared to male (40.6%).

Taste evaluation

The response of the panelist on the selected sweetpotato accessions tested shows most of the accessions had sweet taste. Offa2 had excellent taste. Bodija, Ladele, PkS. Pk3, Doris, Yau, Mother’s Delight, Ex-Igbariam, Offa, Molete, Felicia NN. BD. and PK55 had good taste while Omini, Dammy, Oja Oba, Sango, Felicia, King J, Orita, BV and PK66 had fair taste, Ojoo had poor taste as shown in Figure 1.

Texture Evaluation

Figure 2 presents the variations in texture as described by the panelists, where most of the accessions were soft in texture. Bodija, Pk5, Mother’s Delight, Sango, Offal, Molete, and Felicia had hard texture. Ladele, Omini, Dammy, Pk3, Offa2, Oja Oba, Doris, Yau, Ex- Igbariam, Usman Felicia NN, Ojoo, King J, BD, BV, and Pk66 had soft texture. Orita, Pk55 had very soft texture.

Table 2: Socio economic characteristics of consumers

Characteristics		Frequency	Percentages (%)

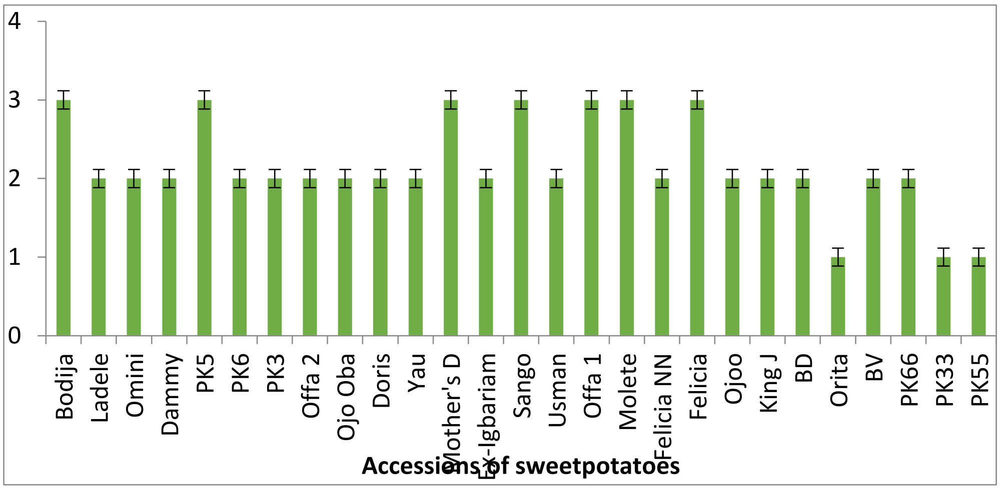

Figure 2: Texture of 26 accessions of sweetpotato

Key: 1 = Very soft (texture); 2 = Soft (texture); 3 = Hard (texture); 4 =Very hard (texture)

Flavour Evaluation

The outcome of the response of panelists on flavour of twenty-six accession of sweetpotato where most of the accession had good flavour. Usman accession had excellent flavour, Bodija, Ladele, Pk5, Pk3, Offa 2, Doris, Orita, Yau, Ex-Igbariam, Mother's Delight, Offa, Molete, Felicia NN, Felicia, and BV accession had good flavour. Omini, Dammy, Oja Oba, Sango, and PK 66, accession had fair flavour, Ojoo had poor flavour as shown in Figure 3.

ISSN: 2814-0508

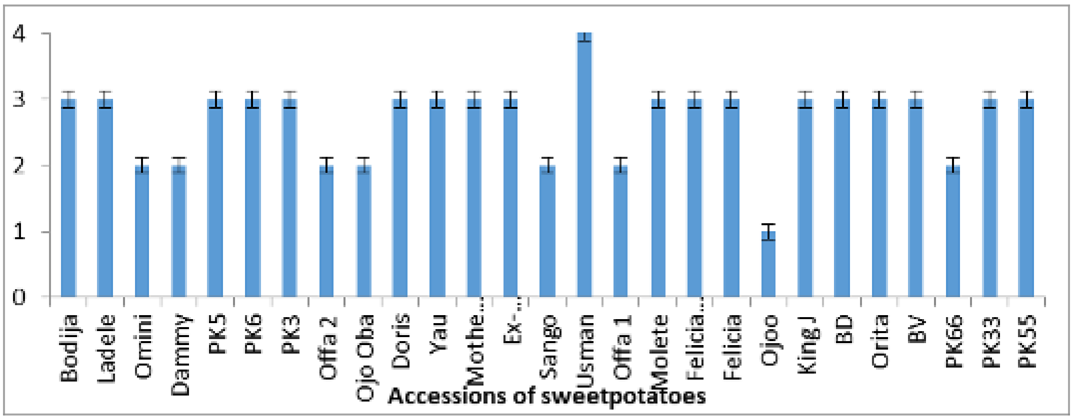

Figure 3: Flavour of 26 accessions of sweetpotato

Key: 1 = Poor; 2 = Fair; 3= Good; 4= Excellent

Appearance

The appearance of twenty-six accession of sweetpotato evaluated were good. Pk6, Pk3, Yau, and Felicia NN accessions had appealing appearance, while Ojoo had poor appearance as shown in Figure 5.

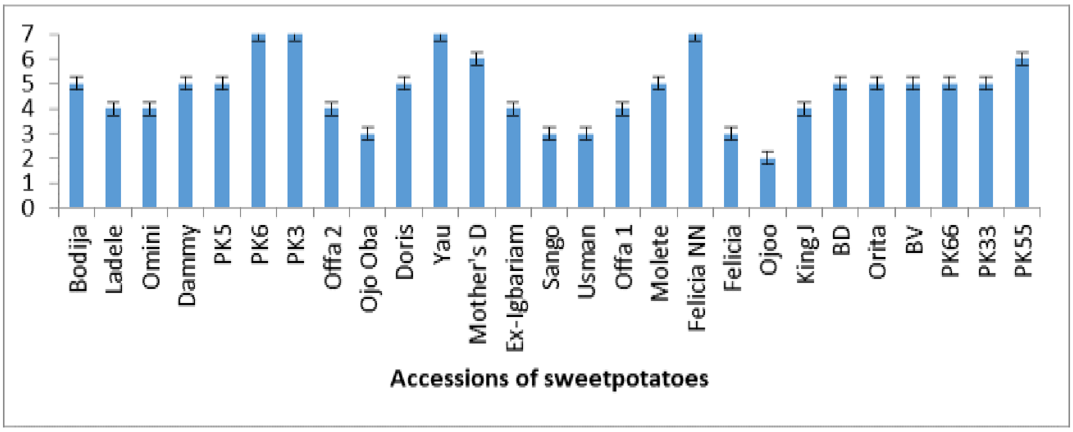

Figure 5: Appearance of 26 accessions of sweetpotato

Key: 1 = Dislike very much; 2 = Dislike extremely; 3 = Dislike moderately; 4 =Neither like or dislike; 5 = Like moderately; 6 = Like very much ;7 = Like extremely

Overall acceptability

The result obtained from the response of panelists showed that the acceptability of the accessions varied from each other where Offal had the highest acceptability rate, the accession was extremely liked, followed by Ladele, Felicia NN, BV accessions which were liked very much, accessions with the lowest rating are Ex-Igbariam and Sango which were disliked moderately (Figure 6).

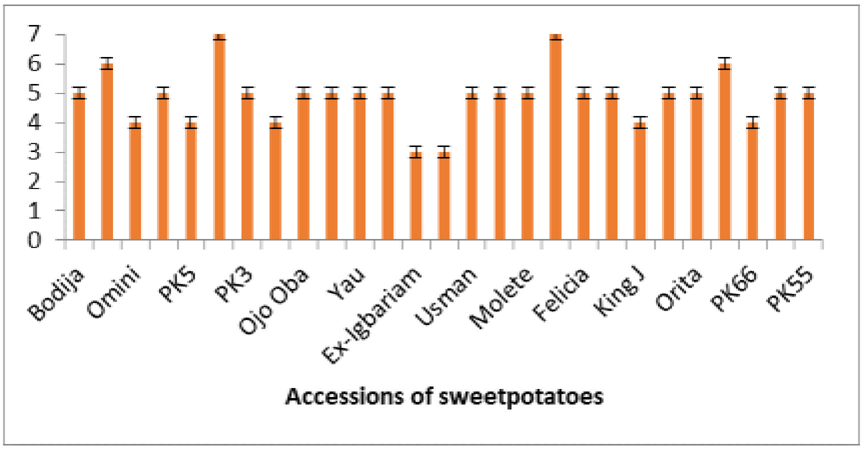

Figure 6: Overall acceptability of 26 accessions of sweetpotato

Key: 1 = Dislike very much; 2 = Dislike extremely; 3 = Dislike moderately; 4 =Neither like or dislike; 5 = Like moderately; 6 = Like very much; 7 = Like extremely

DISCUSSION

One of the world's greatest challenges is to secure adequate food that is healthy, safe and of high quality for all (Hunter and Fanzo, 2013). Sweetpotato is a nutritious food, low in fat and protein, but rich in carbohydrate. Both tubers and leaves are good sources of antioxidants (Teow *et al*., 2007). Sweetptato is grown for its multipurpose use. Both the root and vines are used for human food and animal feed. There has been a great deal of breeding effort focusing on developing sweetpotato varieties fortified with minerals for human consumption and not on vine yield. The mean age of the respondent was 24.5 which implies that majority of the respondents were youths, which implies they are willing and ready to try new products. Hence, the demand for new varieties to enhance nutrition and flexibility/diversity.

Several studies have shown that there are varieties with a potential of producing both root and forage (Lukyu and Agili, 2013). Therefore, the exposure of households to new varieties of sweetpotato will help to improve the livelihood of farmers, food security and nutrition of the rising populace. This was also supported by (Almekinders and Hardon, 2006) who reported that dissemination of dual purpose varieties could help improve the livelihood of herdsmen. Colour variability and taste of OFSP in relation to its acceptability is a prevalent problem which needs urgent intervention. Therefore, there is need to improve on the root and develop acceptable products needed to combat the prevailing hunger with increased population while improving profit maximization for farmers.

CONCLUSION AND RECOMMENDATION

Sweet potato is rich in diversity with colours ranging from cream to purple and orange. Majority rated offa accession with excellent taste with hard texture. While the flavor of Usman was preferred to others. The appearance of PK5, PK6, PK55, Felicia NN and Yau was also liked very much compared to others. Conclusively, PK6 and Felicia NN was accepted by majority. Conclusively, more enlightenment need to be conducted on the production, diversity and nutritional benefits of sweet potato accessions, both for the elites and rural community who may not be familiar with its availability and production.

ABSTRACT

Building the ability of stakeholders to follow appropriate procedures for production and processing of African bush mango is important for improved production/processing and increased income. This study thus assessed knowledge gained by participants during a capacity building programme on Irvingia spp. production and processing in Imo and Abia states. Stakeholders selected for the training were from an earlier need assessment/situation analysis conducted in Imo and Abia states. Aspects of the training taught were from propagation to field maintenance as well as processing using a manual Irvingia decorticator. Data was collected from stakeholders using structured questionnaire and analyzed with descriptive and inferential statistics (t-test). Most of the participants were male (54.6%), married (86.9%), and had up to 13 years of Irvingia production experience. However, 86.9% of the stakeholders were not aware of the manual Irvingia decorticator. The t-test result showed a significant difference in participants' pre and post knowledge assessment carried out. This implies an increase in knowledge of the subject matter was observed among the participants; this is expected to lead to improved production and processing of Irvingia kernels.

Key words: African bush mango, processors, producers, knowledge assessment, *Irvingia* manual decorticator

INTRODUCTION

African Bush Mango (*Irvingia spp.*) is a tropical African fruit tree that is highly valuable and an important Non-Timber Forest product in West and Central Africa (including Nigeria) with large production and economic potentials. It contributes to alleviating the food, nutritional and health needs of the people particularly in Africa (Okolo et al, 1995, Chadare et al, 2010, Ahenkan and Boon, 2011, Sossa-Vihotogbe et al, 2012). The fruit tree also plays a prominent role in the livelihoods of both urban and rural dwellers in and around the world (Tabuna, 2000). There are two types- the bitter and sweet Irvingia (*Irvingia wombulu* and *Irvingia gabonensis)* but the bitter type has more value and commands higher price in international/regional trade. *Irvingia* species are highly medicinal and used as thickener for soups mostly relished by people in Southern Nigeria. They are also used in the cosmetic industry (Lesley and Brown, 2004). African bush mango is mostly found growing in the wild and its commercial production is limited (Lowe et al, 2000). This is the reason for having more people involved in its collection than production thus; it is important to train *Irvingia* producers/collectors how to propagate the crop for optimum production.

Irvingia spp kernels are obtained by cracking the nuts which involves separating the kernels from the dried nuts. Processors make use of stone and knife to manually crack the nuts to obtain the kernels; a method which leads to injury of the processors' fingers as well as drudgery. This method also leads to reduction in the quality and quantity of African bush mango kernels available for sale by the processors. As a result, it is important to find a means of processing the nuts in a way that will retain the quality and quantity of kernels obtained (Busari et al, 2019). Studies such as Diabano, 2009, Busari et al, 2019 have carried out research on the design, fabrication and evaluation of performance of mechanical *Irvingia* nut crackers. Diabano 2009's study showed that moisture content of the Irvingia nuts did not affect cracking ability of the nuts. On the other hand, Busari et al, 2019 noted that cracking efficiency of the mechanical nut cracker was higher when the nuts used were of lower moisture content. The National Horticultural Research Institute, Mbato outstation, Okigwe designed and fabricated a manually operated *Irvingia* decorticator to reduce the drudgery associated with processing *Irvingia* nut and increase its market value. Owing to the fact that African bush mango processors are faced with these identified challenges, it is crucial to conduct capacity building activity on the use of this manually operated decorticator in a bid to introduce it to processors in the area.

Capacity is the ability of someone or a group of people to do something following appropriate procedures (UNDP, 2002). According to the Farmer-to-farmer blog (2015) of agrilinks.org, "capacity is the ability of people, organizations, and society as a whole to manage affairs successfully, to achieve goals and to satisfy the rights or expectations of citizens, customers and other stakeholders". Capacity of individuals can be developed by improving competence in both technical and soft skill which in turn contributes positively to effectiveness (Farmer-to-farmer blog, 2015). It involves the transfer of new knowledge, skills and competencies to individuals or groups in order to carry out their activities more efficiently and resourcefully (Yanseen et al, 2015). Learning and training (or capacity building) in agriculture (horticulture) contributes to poverty reduction by equipping farmers and other stakeholders with knowledge and skill required by them to raise their productivity and income (Ogundele et al, 2012) thus achieving improved livelihood. Capacity building and training are important components of research-for-development (Gordon and Chadwick, 2007). There are 3 levels of capacity building which are individual, organizational/institutional and societal (Kumari and Khanduri, 2019). It is important that training/capacity building activities should be on the needs/demand of the individuals/groups to be trained. Thus, arising from a needs assessment/ situation analysis on the African bush mango value chain carried out earlier in some states in Southern Nigeria (Abia, Imo and Rivers states), capacity building on the production and processing of *Irvingia spp*. was identified as an area of intervention. The situation analysis revealed that stakeholders (producers and processors) had limited access to improved seedlings and processing method considering the economic and health benefit of African bush mango kernels traded in the study area and beyond. As a result, a capacity building activity was conducted for selected stakeholders during which an assessment of knowledge gained on the propagation and processing of Irvingia fruits using *Irvingia* manual decorticator (processing machine/ nut cracker) was carried out.

MATERIALS AND METHODS

Participants were trained in two different locations- Mbato, Okigwe in Imo state and Abia state. The locations are accessible to the African bush mango producers and processors who were trained. Participants for the training (*Irvingia* producers and processors) were those present during the situation analysis earlier conducted. They were contacted through the Agricultural Development Programmes in Imo and Abia States. Also in Imo state, participants were from the neighbourhood of the National Horticultural Research Institute's sub-station at Mbato, Okigwe. The training covered four aspects:

- Propagation of Irvingia
- Seed extraction
- Nursery establishment and management
- Field establishment and other management practices
- Processing *Irvingia spp*. using the manually operated *Irvingia* decorticator

Practical demonstration was done and the participants had the privilege of hands-on experience on the use of the manually-operated *Irvingia* decorticator. To assess the immediate change in knowledge of individuals trained on the subject matter, knowledge gained was evaluated before and after the training and analyzed using the t-test.

RESULTS AND DISCUSSION

Profiling the participants' socio-economic characteristics, the study (Table 1) showed that 165 participants were trained in Imo and Abia states; however, only 130 completed pre and post evaluation questionnaire retrieved from the participants trained were found analyzable. A larger percentage of the participants were males (54.6%), married (83.9%) with average family size of 7 household members (6.6±2.3) and age of 50 years (49.5±11.7) respectively. Most of them had at least secondary education (65.4%) with an average of 13 years (12.8±9.6) of farming experience. Also, more than half of the participants (63.8%) belong to an association. This is supported by the study of Chah et al, 2014 which found that 56% of Irvingia farmers in Enugu state (part of southern Nigeria) were males, having on the average, a household size of 6 members and 16 years of experience in Irvingia farming. A sizeable proportion was not aware of the manual *Irvingia* decorticator (86.9%). However, 79.2% registered their willingness to use the manual decorticator. This implies that most of the stakeholders in *Irvingia* value chain trained were married, educated and experienced farmers. They were not aware of the manually operated *Irvingia* decorticator but were willing to use it for processing *Irvingia* nuts.

Pre and Post Knowledge Assessment of participants

There was an increase in the overall mean scores of participants when their knowledge was assessed using the pre and post evaluation questionnaire (4.4±2.3 versus 5.3±2.5 for pre and post scores respectively) (Table 2). The t-test result showed significant difference in the knowledge of participants before and after the training sessions (t=4.1, p=0.000). This revealed that participants' knowledge increased after the training. This agrees with the finding of Olajide-Taiwo et al, 2018 who found a significant difference in the pre and post knowledge assessment of participants during a training programme on ginger and turmeric production techniques in Oyo state, Nigeria. Thus, the training programme is expected to lead to the use of improved seedlings for production and manual *Irvingia spp* decorticator which will increase *Irvingia spp* production, processing and ultimately income of the stakeholders.

Furthermore, participants stated that apart from the process of seed extraction taught as well as the practical demonstration on the use of the manual *Irvingia* decorticator, they benefitted from the training sessions on cultivation of *Irvingia*, and its medicinal and industrial uses among others.

Table 3: Pre and Post Knowledge Assessment of participants

Score	Mean	Standard Deviation	Std error Mean	Df	T value	Sig level

CONCLUSION AND RECOMMENDATION

This study assessed the change in knowledge of participants during the capacity building programme on production and processing of African bush mango (*Irvingia spp*.) held in Imo and Abia states. Capacity building is important for enhanced sustainable development while a pre and post training knowledge assessment is required to establish the immediate change in knowledge of the participants as a result of the training. Most of the participants were male (54.6%), 65.4% had at least secondary education, 86.9% were married while most of them had 13 years of experience also, 89.6% were not aware of *Irvingia spp.* manual decorticator. Findings revealed a significant difference in participants' knowledge in the pre and post knowledge assessment conducted. Moreover, the participants stated that they are willing to make use of the knowledge gained during the training. This is expected to improve Irvingia production and processing in the study area. In order to assess the outcome of knowledge gained during the capacity building programme, monitoring of the participants is imperative.

ABSTRACT

The study examined the economics of invirgia wombolu "Ogbono" kernel processing in Ogbadibo Local Government Area of Benue state, Nigeria. Multistage and random sampling techniques were used to select 100 respondents for the study. Data were collected with the aid of structured questionnaire and personal interview. Analyses of data were achieved using descriptive statistics, cost and return and multiple regression and Likert-scale model. The result of the study shows that Ogbono kernel processing was a profitable business with a net return on investment value of about 57k for every ₦1.00 invested in the business. Females (62%) were mostly involved in the processing exercise than males (38%) with average age of 35 years and have 15 years of experience in processing with an average annual income ₦125, 500.00 from the business. More so, high cost of Ogbono fruit and labour had affected the farmers 'output. Though the observed constraints such as injury sustained during cracking of the kernels and high cost of labour had seriously affected the processing of Ogbono kernel in the area. It was therefore recommended that the farmers should form a cooperative society to enable them attract the attention of both government and non-governmental organization that can intervene by providing and training the farmers on any available modern processing technique. This cooperative society will also help them to get meaningful financial assistance from government or other non-interest based financial institutions.

Key words: irvingia wombolu, "ogbono", processing, gross margin, profitability.

INTRODUCTION

Irvingia gabonensis and *Irvingia wombolu* commonly known as African mango, bush mango or wild mango is an important Non-Timber Forest Products (NTFPs) that has been a valuable source of income to the rural people and the urban poor in Nigeria. It belongs to the family *Irvingia*ceae (Arowosoge, 2017). There are seven listed species of the *Irvingia* genus; six of which are native to tropical Africa and one species native to South-east Asia. Of the six species native to tropical Africa only two are economically important: *Irvingia gabonensis* var. *gabonensis*, and *Irvingia gabonensis* var. *excelsa* which was renamed to be *Irvingia wombolu* (Harris, 1996). The two are very similar with the exception that *Irvingia gabonensis* has a sweet edible pulp (mesocarp) and the stone is usually split to reveal its kernel which is the product that is used for soup thickening in most parts of Nigeria but the kernel is less slimy while *Irvingia wombolu* has a bitter inedible pulp and the fruit stone is also extracted to produce the kernel which is often known as '*Ogbono* which is slimier (Okafor, 1975). It is worthy of note that in Nigeria, both the pulp and dry kernel of *Irvingia gabonensis* are traded while only the dry kernel of *Irvingia wombolu* are traded. However, *Irvingia wombolu* kernel commands more price and demand due to the high slimy consistency produced in soup making when compared with *Irvingia gabonensis* kernels (Awe et al, 2012). *Irvingia* trees are a valuable source of income for West and Central African farmers. The fruits are sold, but by far the most important product is the kernels, which fetch a price several times higher than the fruits. The trade in kernels not only benefits the producers financially, but also generates income for traders (Babalola and Agbeja, 2009).

Ogbono is a wonderful soup thickener and flavouring ingredient in many parts of Nigeria and Africa in general, it is a very lucrative source of income and essential raw materials for the pharmaceutical industries and most importantly, potential foreign exchange earnings. Joseph (1995) listed the potential industrial applications of *Irvingia* kernel oil/fat to include cooking oil, margarine, perfume, soap and pharmaceuticals. The pulp can be used for the preparation of juice, jelly and jam. The kernel is also used in making fatty paste called "dika", which is the major ingredient in making of "Gabon Chocolate" or "dika bread" (Ugwumba *et al*., 2013). Irvingia shells are used as fire wood materials when fully dried.

Irvingia species can be found in the forests (wild) and can be domesticated in the farms or gardens. Irvingia fruit, for fresh eating and for their kernels could be picked from forests, farms or gardens.

Many families depend on picking of irvingia fruit as supplementary source of income for their survival, and some families use to buy from others or people that picked and don't want to process them. Picking of irvingia fruit from the field takes place between December to April for *Irvingia wombolu,* May to July for *Irvingia gabonensis*. Pickers of irvingia fruit are mostly children and women, and few young and adult males. The women and children are sometimes restricted to pick from nearby farms and nearby village forests only. While the adult and young males are involved in picking from any available forests or farms, which could be daily, two or three days intervals or even on weekly basis. Sometimes the fruit are processed in the forests or in the farms to reduce the load weight when carrying it home, however, women and children usually feel more comfortable when processing irvingia fruit at home than in the bush or farms for security reasons (Ladipo et al., 1996). Processing of "Ogbono" kernel is seasonal and so, the processors engage in other employments such as trading, farming and art work.

Processing of irvingia kernels in the study area is highly constrained by many factors particularly the use of traditional processing techniques. This situation made it necessary for this study to determine the economics of *invirgia wombolu* "Ogbono" kernel processing with the following objectives; to describe the socioeconomic characteristics of the "Ogbono" kernel processers in the study area; establish the profitability of "Ogbono" processing in the area; and identify constraints to processing.

MATERIALS AND METHODS

The study was carried out in Ogbadibo Local Government Area (LGA) Of Benue State, Nigeria in 2021. It is one of the 23 LGAs of Benue State and among the nine LGAs in agricultural Zone C. Ogbadibo LGA is made up of three districts which are Otukpa, Orokam and Owukpa. It Consists Of 16 Communities which include Ai-Oono 1, Ai-Oono 2, Ai-Oono 3, Olachagbaha, Ai-Oodo 1, Ai-Oodo 2, Orokam 1, Orokam 2, Orokam 3, Itabono, Ehaje 1 and Ehaje 2. The LGA covers an area of about 598km^2. The estimated population was 130,988 people in 2006 population census. The area is located between latitudes 7^o5^1E 21^{11}N and longitudes 7^o38^1 60^{11} E . It is bounded in the north by Olamaboro LGA of Kogi state, Isi-Uzo LGA of Enugu state to the south, to the west by Udenu and Igbo-Eze North LGA of Enugu State and Okpokwu LGA of Benue state to the east. The people produce crops like cassava, yam, beniseed, bambara nut, melon, oil palm, palm wine, Ogbono, groundnut and so on. Multistage and random sampling techniques were used to select 100 respondents for the study. The first stage involved the selection of ten communities out of the thirteen communities in the area. Stage two entailed a selection of two (2) villages from each of the ten selected communities to get 20 villages. Finally, five Ogbono kernel processing farmers from each of the 10 villages were selected to obtain a total of 100 respondents. Primary data were collected using copies of questionnaire which were administered to the respondents and oral interview.

Analytical models

Descriptive statistics such as means and percentages were used to analyze data on socioeconomic characteristics of the respondents. Gross margin and Multiple Regression analysis was used to explain the profitability of the enterprise while Likert-scale was used to analyze the constraints.

GM=TR-TVC

NPI (Profit) =TR-TC (TVC+TFC)

Where

GM= Gross Margin (N), TR=Total Revenue (N), TC= Total cost, TVC=Total Variable Cost (N)

and NPI=Net Processing Income (Profit)

The multiple regression models used to establish the profitability of the enterprise is implicitly given as:

OOKP =f(COf, COL, PRT)

Explicitly, the model is given as:

$OOKP = \beta_o + \beta_1 COf + \beta_2 COL + \beta_3 PRT + e$

Where

COf= Cost of Ogbono fruit, OOKP= output of Ogbono kernel Processing (kg), COL=cost of labour

PRT=processing technology (dummy: traditional method=0, improve technology=1) and e_i=error term

Four functional forms of regression model (linear, exponential, semi-log and double-log) were tried with the data. The one that gave the best fit in terms of value of co-efficient of multiple determinations and number of significant variables was chosen as the lead equation. The functional forms are given as:

Linear: $OOKP = \beta_o + \beta_1 COf + \beta_2 COL + \beta_3 PRT + e$, Exponential; $\log OOKP = \beta_o + \beta_1 COf + \beta_2 COL + \beta_3 PRT + e$, Semi-log: $OOKP = \beta_o + \beta_1 COf + \beta_2 COL +$

β_3PRT+e and Double-log: log OOKP = $\beta_o+\beta_1$COf + β_2COL + β_3PR +e

Likert –scale model

$$X = \frac{ns}{N}$$

Where

n=number of respondents, s= Likert scores and N= total number of population

Decision rule; reject for factors scored ≤2.5 otherwise accept.

RESULTS AND DISCUSSION

Result presented in table 1 shows that majority of the irvingia kernel processors were females (62%), and 38% were males, indicating that females were more involved in Ogbono kernel processing than males in the area which is collaborated by the findings of Ugwumba et al, 2013 that females are more in the processing of Ogbono kernel than their male counterpart. The average age of the farmers was 35years, which is a good mean age for meaningful Ogbono kernel processing; also, majority (61%) of the farmers were married and 24% were single and the average household size was 13 members. Again, greater percent (64%) and (24%) had secondary and tertiary education respectively. The mean for experience in processing was 15 years and all (100%) the farmers used both family labour and hired labour. Most of the farmers (58%) had no contact with any extension agents concerning Ogbono kernel processing technique while 42% of them had actually been in a discussion with extension agents and none of the respondents (100%) belongs to any Ogbono co-operative organization. Again, all the respondents (100%) sourced Ogbono fruit both from the forest and farms while engaging the traditional processing technology (100%) only. However, the average annual farm income from Ogbono kernel processing was N125, 500.00.

Gross margin analysis was adopted in analyzing costs and returns in Ogbono kernel processing in the area. Results obtained in table 2 shows a gross margin, net processing income and net return on investment values of ₦ 458, 650.25; ₦ 312, 150.00 and 0.5685 each. The net return on investment value of 0.5685 implies that the respondents returned about 57k for every ₦1.00 invested in the business implying that Ogbono kernel processing is a profitable business in the study area (Table 2).

The four forms of multiple regression analyses were employed to estimate Ogbono kernel processing output. From the values of estimated parameters such as coefficient of multiple determination, R^2 and number of significant parameters, double-log function was therefore chosen and result is presented in table 3. Cost of fruit was negatively signed and statistically significant at 1% level, this implied that the variable negatively influenced the output of Ogbono kernel processing in the area; this means that the higher the cost of Ogbono fruit purchased the lesser the output of the kernel processed. This is because increase in cost of a produce usually; result to decrease in the quantity demanded of the same produce. Thus, the aprior expectation was met. Again, cost of labour was negatively signed and statistically significant at 5% level, meaning that increase in the cost of hiring labour will lead to decrease in the quantity of Ogbono kernel processed. Hence, the aprior expectation was met. However, processing technique was positively signed and statistically significant at 1% level, this is because the farmers used majorly traditional processing technique involving machetes, knives, basins and dried wood which have enabled them to achieve their level of output in the business. That is, this method of processing has good relationship with the output of Ogbono kernel and had positively influenced the income of the farmers. Thus, the aprior expectation was met. Meanwhile, the high value of R^2 implied that the independent variables examined significantly caused about 86.8% change in the output of Ogbono kernel processing in the area. The remaining 13.2% was due to error. The F-statistics value of 341.31 was significant at 1% level and so, confirmed the overall significance of the regression analysis. Durbin- Watson statistic value of 2.01 indicated absence of autocorrelation among the factors observed.

Table 4, shows factors that significantly militated against Ogbono kernel processing in the area include, finger wounds when cracking the kernels(x=3.75) which usually occur when the fruit slicing target is missed or when the machete is wrongly placed on the fruit, high cost of labour (x=3.46) that could be associated with high inflation rate in the country or scarcity of young people in the business as a result of the high level of drudgery involved. Rough and stained palms when handling the monocarp (x=3.44) that is always slimy and yellowish in colour, lack of capital (x=3.28) associated with poor level of income in the area, waist pains, shoulder pain, others (x=3.20), and high cost of transportation (x=2.74) in the country.

CONCLUSIONS AND RECOMMENDATIONS

Ogbono kernel processing was a profitable business with net return on investment value of about 57k for every N1.00 invested in the business though so tedious because of the traditional processing technique that was majorly engaged in the study area. Females were mostly involved in the processing exercise than males with average age of 35 years and have good years of processing experience of 15 years, while, the average annual income from the business was N125, 500.00. More so, high cost of Ogbono fruit and labour had affected the farmers'output, however, the traditional processing technique used had enabled the farmers to achieve their certain level of output. Among the various constraints experienced by the respondents in the processing of Ogbono in the study area are injury encountered during cracking, high labour cost, stained palms etc. It was therefore recommended that the farmers should form a cooperative society to enable them attract the attention of both government and non-governmental organization that can intervene by providing the farmers with any available modern processing technique. This cooperative society will also help them to get meaningful financial assistance from government or other interested based financial institutions.

Table 4: Factors Constraining Ogbono kernel processing

Factors	Mean score	Decision
Finger wounds when cracking the kernels	3.75	Accept
High cost of labour	3.46	Accept
Rough and stain palms when handling the mesocarp	3.44	Accept
Lack of capital	3.28	Accept
waist pains, shoulder pain, and others	3.20	Accept
High cost of transportation	2.74	Accept

ABSTRACT

One of the major objectives of Cocoa Research Institute of Nigeria (CRIN) is to investigate the effective utilization of the crops and their by-products, and the feasibility of small-scale production of such end-use products. Based on this objective, cocoa pod husk (CPH) is one of the major by-products of cocoa and has been utilized effectively by CRIN through its inclusion in poultry feeds. The adopted village and school concept was a collaboration between Agriculture Research Council of Nigeria (ARCN)/West Africa Agricultural Productivity Programme (WAAPP) and CRIN. The poultry project in the CRIN adopted village and school is to encourage secondary school students to develop interest in agriculture and for farmers to increase their livelihood activities by reducing the cost of buying layers' mash. This technology was demonstrated in CRIN adopted village such as Aba-Agbo Community in Oyo state, and CRIN adopted school such as Mamu Community Comprehensive High School in Ogun state. The inclusion of CPH in layers' mash reduced the quantity of maize in the formulated feed by 20% (most especially in layers' mash). This was demonstrated by feeding equal number of birds with conventional feed (control) and CPH-based diet for 16 months (experimental). The result revealed that about N495 was saved on every 25kg of CPH-based feed, compared to conventional feed. Egg production was also similar to that of control. This resulted in a significant decrease in feed cost on CPH-based feed when compared to conventional feed, thereby increasing the farmers' profit margin. However, COVID-19 pandemic which eventually led to lockdown nationwide, posed some challenges such as theft of experimental eggs and birds as well as transportation restrictions to the project. In conclusion, the idea of substituting quantity of maize with CPH in poultry diets reduces the production cost and increased farmers' income. It is recommended that CPH may be used as a part- substitute for maize in poultry feed.

Key words: Farmers, Students, CPH, Poultry feed, Adopted Village and School.

INTRODUCTION

Cocoa-Pod Husk (CPH) is a by-product of cocoa and it forms about 80% of the cocoa fruit. It is essentially a waste product except for the negligible amount used in the manufacture of local soap and feeding of livestock (Eghosa *et al.*, 2010). CPH is usually an under-utilized agro-waste from cocoa, which could serve as good nutritional source for monogastric animals (Adeyeye *et al*, 2017). It is estimated that 0.8 to 1.0 million tons of CPH is generated annually in cocoa farms in Nigeria (Ojeniyi, 2006). Very little of the potentials locked up in this by-product have been exploited (Egbe and Olubamiwa, 1989). However, CPH can be incorporated into layers' diets to serve as a substitute or reduce the quantity of maize. The inclusion of CPH in layers' mash will reduce quantity of maize by 20%, thereby reducing the ever soaring cost of maize. The increase in the price of conventional feed ingredients, especially maize constitutes the primary cause of the rise in animal feed production cost, subsequently making animal protein cost very high (Adeyeye *et al*, 2017). The replacement of one or more major ingredients in conventional feed will significantly reduce the production cost of animal feed thereby increasing access to animal protein (Adeyeye *et al.*, 2017). According to Agunbiade and Olubamiwa (2002), CPH contains protein, energy and fibre, which are important ingredients of livestock feed.

Commercial poultry production provides easily accessible and affordable meat and eggs. About 80% of the world population gets most of their basic nutrients like proteins, fats and vitamins from meat and eggs (FAO, 2009). Presently, in Nigeria and other developing countries, despite the recent relatively rapid expansion in the livestock industry, protein consumption is 75% below the FAO requirement (Ibe, 2000). High cost of animal production results in high cost of animal protein thereby reducing the affordability of animal protein. Therefore, reducing the cost of animal production by using by-products from crops will greatly increase the affordability of animal protein.

The demand for maize increases yearly due to rising population and urbanization, as well as the growing poultry and fish industrial sectors of the economy (Djim koffi *et al.*, 2020). Maize being one of the major ingredients used in producing animal feed is exposed to several production risks, ranging from the disastrous effects of army worms, destruction of several maize farms by grazing cattle, farmers/ herders clashes and effect of climate change and so on. These factors combined have led to a sharp increase in the price of maize, which forms the major ingredient in poultry feed. Hence, a way to curtail the rising cost of feed would be by substituting some quantity maize with CPH, which is almost cost free.

The Agricultural Research Council of Nigeria (ARCN) in collaboration with Cocoa Research Institute of Nigeria (CRIN) initiated the adopted village and school concept in year 2009. The West African Agricultural Productivity Programme (WAAPP) embraced the idea and used it to reposition technologies development and dissemination in all research institutes in the country. This led to the establishment of different intervention projects such as poultry, fishery and arable crops production. The projects were demand driven by the host communities irrespective of the institutional mandates. The major purpose of these projects is to disseminate developed technologies in research institutes to farmers in nearby communities and to encourage youth involvement in agriculture. So to demonstrate this, the inclusion of CPH to replace 20% maize was carried out by CRIN with following specific objectives:

- to encourage the inclusion of CPH in poultry feed formulation,
- to inspire students' interest in agriculture from their tender age,
- to increase the income of farmers by reducing cost of poultry production,
- to encourage students and teachers to be job creators.

MATERIALS METHODS

The study was carried out in Mamu Comprehensive High School in Ogun state and Aba Agbo community, in Oluyole Local Government Area, Oyo state. Both school and the village fall within 5km range to the headquarter of CRIN as stipulated by ARCN. Mamu Comprehensive High School was purposively selected because it represents the school the poultry experiment was conducted and Aba Agbo was purposively selected because of their strong willingness to adopt technologies developed by CRIN. A participatory approach was adopted, with the beneficiaries (Agricultural Science students in Mamu Secondary School and farmers in Aba-Agbo) assisting in feeding the birds, water-supply, as well as providing partial security over the poultry pen. CRIN, in collaboration with ARCN built the poultry house and put battery cages. CRIN supplied the birds, vaccines, partial labour, security including other logistics. The Principal and Agricultural Science Teachers in the School organized students to ensure maximum participation and cooperation. The spaces for the poultry houses were provided by the school authority and farmers with the approval of the village head in Aba-Agbo.

Eighty (80) point-of lay birds (18 weeks) Bovan Brown breed were stocked in two different cages, forty (40) birds per cage. They were fed with conventional feed till 20 weeks to attain optimum laying capacities, after which the two categories of birds were fed differently with CPH-based diet and the conventional feed. Data were taken daily on eggs production, feed consumption, and vaccination in both categories. The results observed were explained using graphs, tables and charts.

Processing of CPH

Disease free and fresh cocoa pod were harvested, broken with the use of a club, after which the cocoa beans and placenta were removed. The husks were chopped into smaller sizes to hasten the drying process. Thereafter the husks were sundried to attain a moisture content of about 10%. The dry processed husks were reduced to smaller particles and stored in sacks on wooden pallets until it was later mixed by formula into the compounded feed.

RESULTS AND DISCUSSION

Table 1 shows the feed formulation for both conventional and CPH-based feed. It can be observed that 20% of the maize in the convectional feed was replaced by CPH in the feed. The 20% of 45 kg is 9kg, so 9kg CPH was included in CPH-based feed unlike in the conventional feed.

Calculations based on price differences between conventional feed and CPH-based feed

Calculation for conventional feed

Price of conventional feed per 25kg bag is N 4,900 (conventional feed comes in a 25kg standard bag)

Price of maize per kg is N220

But in a 100kg of conventional feed, maize constitutes 45kg (check in table 1)

Hence, N220 x 45kg = N9,900

Since there are four 25kg bags in a 100kg bag of feed

Therefore 9,900 / 4 = N2,475

This means that the share cost of maize in a 25kg bag (which costs N4,900) of feed is N2,475, while the share cost of other ingredients isN2,475 (i.e. N4,900 –N2,475)

By this calculation, maize makes up to half or 50% of the cost of a 25kg bag of conventional feed

Calculation for CPH fortified feed

In a CPH-based feed, 20% of maize is substituted with CPH.

20% of 45kg (45kg being the quantity of maize in a 100kg of conventional feed) is 9kg

45kg – 9kg = 36kg

Market price of maize (at the time of execution) was N220 per kg.

N220 x 36kg = 7,920

Since there are four 25kg bags in a 100kg bag of feed as shown above

Therefore 7,920 / 4 = 1,980

This means that the share cost of maize for a 25kg bag of CPH-based feed is N1,980, which is against the original cost of N2,475 for a 25kg bag of conventional feed.

Therefore, a 25kg bag of CPH-based feed is cheaper by N495 (i.e. N2,475 –N1,980) than a 25kg bag of conventional feed

Production record for both conventional and fortified feed with CPH

Table 2 shows the eggs laid by birds fed with conventional feeds and CPH-based feed. It can be observed that egg production dropped significantly in July, 2020 (659), December, 2020 (670) and January, 2021(443), this was due to the diversion of the money realized from sale of eggs to other school projects by the school principal, so birds were not fed properly. This finding corroborates Hagger *et al*. (1989) that found out that feed is the most important single cost item in egg production of laying birds and a reduction in feed consumption will affect the laying capabilities of birds. It can also be observed that egg production increased significantly in February, 2021 (1,268) this was due to intervention by CRIN to supply feeds and some multivitamins to the birds. So egg production peaked up again. Jeroen Visscher, |(2017) confirms that high performance laying birds needs a perfect feeding strategy to maintain the diserable laying performance level.

Table 2: Production record for both conventional and fortified feed with CPH

Chart showing eggs laid by birds fed with conventional feeds and CPH-based feed

Figure 1 shows the result of the egg laid by birds fed with conventional feeds and CPH fortified feed. It can be seen that the difference between the two feeding ingredients is almost marginal. This finding is corroborated by Ashade *et al.* (2010), who observed that 100% maize substitution with CPH had no significant effect on the survival, weight gain, and feed conversion ratio at a reduced cost in the diet of laying birds.

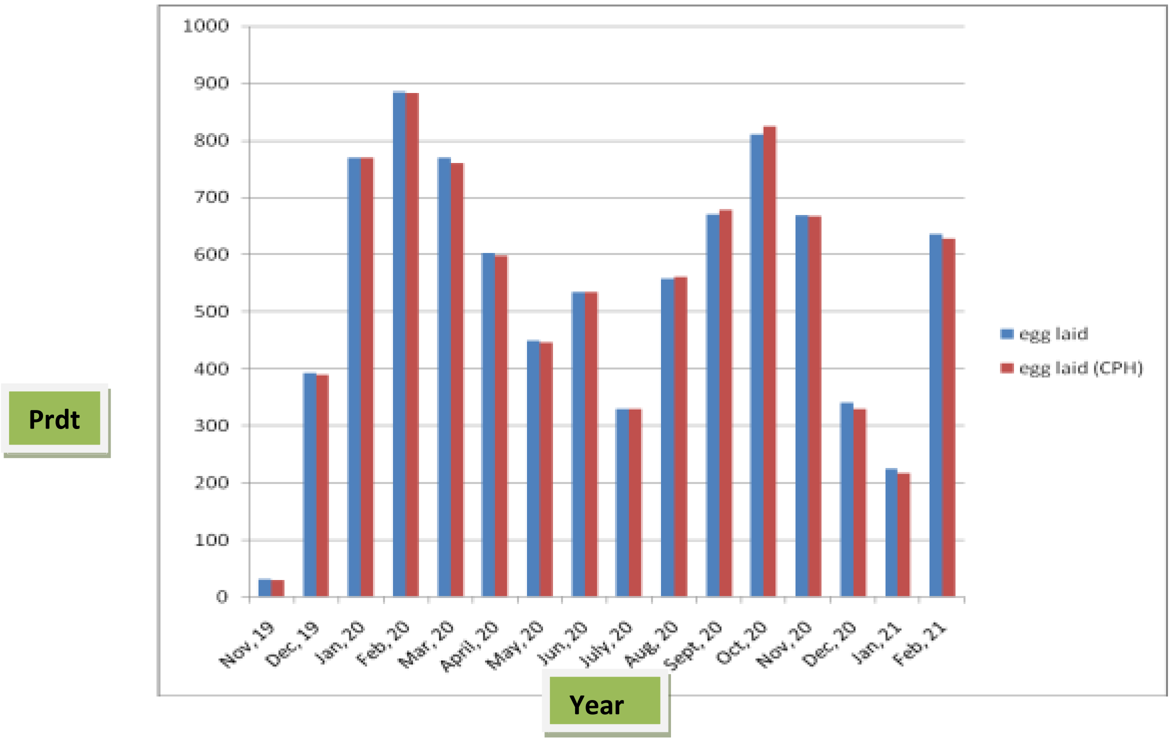

Figure 1: Bar chart showing eggs laid by birds fed with conventional feeds and CPH-based feed

Legend: Prdt represents Egg Production

Pulled eggs laid by both birds fed with conventional and CPH-based feed

The figure 2 shows the egg laid by birds fed with the conventional feed and CPH based feed between November, 2019 and February, 2021.

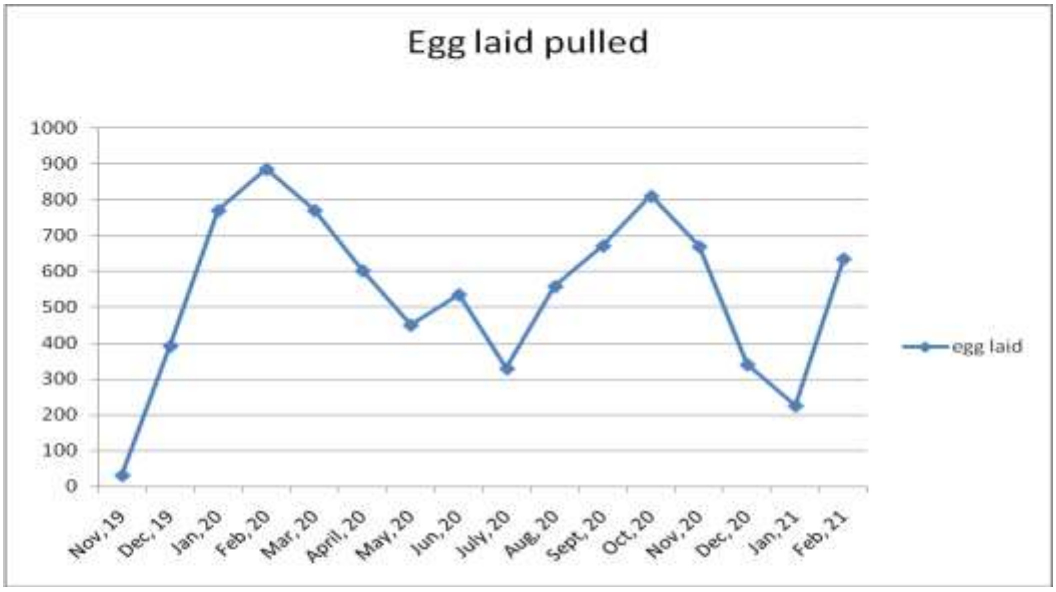

Figure 2: Pulled eggs laid by both birds fed with conventional and CPH-based feed

Source: field survey 2020

CONCLUSION AND RECOMMENDATIONS

The results showed that 20% of maize in conventional feed was successfully replaced by CPH without any significant difference in the production capability of laying hen. This can considerably reduce the cost of production in poultry business, thereby increasing the profit margin of farmers. It is recommended that poultry farmers should embrace the use of CPH to replace the recommended proportion of maize in their compounded feed. Also, more schools and communities should be encouraged to adopt this programme.

ABSTRACT

Capacity building and training is imperative to improve performance of actors in agricultural/horticultural value chain. This is because improved knowledge may translate to enhanced efficiency. The study examined effect of capacity building and training on stakeholders' knowledge acquisition in plantain and pineapple value chain in Delta State. Stakeholders were randomly selected from communities in four Local Government Areas of the state (Ika South, Ukwuani, Ndokwa West and Ndokwa East). Structured interview schedule was used to collect information from 400 participants out of which 354 were found usable. Participants' knowledge in various aspects of plantain and pineapple value chains taught with practical demonstration were determined. Data collected was analyzed using descriptive statistics, T- test and linear regression. Results showed that 88.7% of the participants were male, 81.6% were married, most (34.2%) were within 31-40 years' age group and 91.9% had secondary and tertiary level of education. Majority of the respondents had farming as their primary occupation (85.3%) and 59.6% and 33.9% of the respondents had 1-10 years' experiences in plantain and pineapple value chain respectively. Overall total mean pre and post training score of the participants was 0.41±8.462 and 15.49±1.55 respectively. T-test result showed a significant difference (t = 27.774, p = 0.00) in participants' overall knowledge after training. Educational qualification of the participants significantly affected knowledge gained in the training. The study recommends scaling out of the training to other areas in which the country has comparative advantage in the production of the commodities in order to improve competitiveness of the value chains.

Key words: Capacity building, Knowledge, Plantain, Pineapple, value chain

INTRODUCTION

Plantain and Pineapple are important fruit crops and have high economic value (USDA, 2012). Nigeria has comparative advantage in the production of the commodities; production figure of plantain in 2019 was 3,182,872 tons from 506,766 hectares (FAO, 2021). Plantain is in high in demand and its cultivation is attractive to farmers due to relatively lower labour requirements for production compared to cassava, maize, rice and yam (Kayode *et al*., 2013). Pineapple production on the other hand, could help to ensure food security, job creation, and launch the country on the path of self-sufficiency, and help in improving lives and health of the populace (All Africa, 2011). Nigeria ranked 7th on the list of world producers, as well as the leading pineapple producer in Africa with a production capacity of 1,671,440 tons from 200,911 hectares in 2019 (FAO, 2021). Despite the aforementioned potential of the country in plantain and pineapple value chain, Nigeria production of the commodities remains low when compared to other producing nations (Adegbite and Adeoye, 2015 and Adeoye, 2015). One of the factors that may be responsible for the low performance is lack of technical knowledge on the use of improved technologies in the commodities value chains.

Capacity building is one of the approaches that may be used to achieve poverty alleviation (Rola-Rubzen and Gabunada, 2003). According to Olajide-Taiwo *et al* (2018), training is crucial to equip stakeholders in good agricultural practices and skills. Capacity development is a process of change in which people, organizations and institutions improve their performance and strengthen their capacity in response to changing circumstances (Kumari and Khanduri, 2019). Most of the empirical research/Socio economic research in Plantain and Pineapple value chain has been on economics of production, marketing of the commodities (Adegbite and Adeoye (2015), Adegbite *et al*, (2014). There are very few empirical studies on the effects of capacity building and training on stakeholders' capacity to improve Plantain and Pineapple commodity value chain. The objective of the study is to determine the effect of capacity building on knowledge acquisition among plantain and pineapple value chain actors in Delta State. Specifically, the study describes the socio economic characteristics of the respondents; determine the pre and post training knowledge about plantain and pineapple value chain and determine the factors responsible for knowledge acquisition through capacity building/training among the respondents.

MATERIALS AND METHODS

The study was conducted in Delta state, Nigeria. It is situated in the South-South geo-political zone with a population of 4,112,445. The state has a total land area of 16,842 square kilometers (6,503 sq mi). Delta State consists of 25 Local Government Areas. A total number of 400 trainees were selected from farmers' and youth organization in 4 local governments noted for plantain and pineapple production using multistage sampling technique. But, 354 questionnaires were found useful for the study. Aspects of theoretical and practical demonstration on Plantain and Pineapple value chain covered were: Rapid multiplication Technique of Plantain and Banana sucker production; Managing Pests and Diseases in Plantain production, Management of Plantain wastes, Pineapple value addition, Water Resources Management for Plantain and Pineapple, Profitability of Plantain and Pineapple value added products and Basic Book Keeping for good business management. Data on socio-economic characteristics and other farm specific variables were collected from the farmers. Knowledge of the respondents about the training content was determined before and after training. Data were analysed using descriptive statistics such as frequencies, means and percentages for socio-economic characteristic of the farmers and their production activities. T test was used to examine significant difference in the knowledge level of the participants before and after the training. Linear regression was used to examine factors responsible for knowledge acquisition through capacity building and training among the respondents.

RESULTS AND DISCUSSION

Most of the participants were male (88.7%) while 11.3% were female, married (81.6%) and within 31-40 years of age (34.2%). Majority of the trainee had secondary and tertiary level of education (91.9%) indicating that they may appreciate significance of training in improving performance along commodity value chain. A large number of the respondents had farming as their major occupation (85.3%). Approximately 60% and 33.9% of the respondents had 1-10 years of experience in plantain and pineapple farming respectively. The dominant source of planting materials was from the open market (49.7%) (Table 1).

T test showing Difference between Post and Pre training knowledge score among the respondents

The mean overall score of pre-training evaluation was 0.41±8.46 while that of post training evaluation was 15.49±1.55 (Table 2). This shows that the mean knowledge of participants increased after the training. Moreover, there was a significant difference in the overall pre and post training scores of the participants as revealed in the t-test result ($t=27.74$, $p=.000$). This indicates that knowledge/skills were acquired by the participants in the course of the training programme. Skills learnt are expected to be put to productive use by the participants. Similarly, Olajide-Taiwo *et al.* (2018) also found significant difference in the knowledge of participants trained on ginger and turmeric production techniques indicating that knowledge gained may be utilized to improved production of the commodities.

Factors responsible for knowledge acquisition through capacity building/training among the respondents

Result of the linear regression analysis (Table 3) showed that the educational level of participants had a positive relationship with knowledge acquisition and was statistically significant (Table 3). The positive relationship showed that an additional year in school may lead to increase in the knowledge acquisition of the participants in plantain and pineapple value chain. Wongnaa *et al* (2019) also found a positive and significant relationship between educational level of farmers and vegetable production in Ghana. The coefficient of age was negative and statistically significant at 5%. This implies that the more advanced in age the respondent are, the less knowledge they may acquire through training.

CONCLUSION AND RECOMMENDATIONS

The importance of capacity building and training in ensuring improved performance and sustainability

ISSN: 2814-0508

of agricultural/horticultural value chain cannot be over emphasized. The study showed that most of the participants in plantain and pineapple value chains in Delta state were male, within the active age group and is farmers with 1-10 years' experience in the commodities value chain. There were significant differences in the knowledge gained by the participants on all the aspect taught after the training. Educational qualification was found to have significant relationship to the total post training score/knowledge gained by the participants. The study recommends intensification of the training and scaling out of the training opportunities to other areas of comparative advantage in Plantain and Pineapple value chain to improve the contribution of the commodities to food security, economic empowerment, employment generation and sustainable livelihood.

ABSTRACTS

Training workshop is an essential ingredient in improving stakeholders' knowledge along agricultural value chain. The study assessed effect of exposure to training workshop on participants' knowledge on ginger and turmeric value chain in Oyo state. Participants were selected with the assistance of the Agricultural Development Programme (ADP) in Oyo State. Data were collected from 83 respondents using interview schedule and analyzed using descriptive and inferential statistics. Majority (65.1%) were male, married (83.1%), within 50-59 years (30.7%) with 1-10 household members (69.9%) and most (54.2%) had tertiary education. Respondents were mostly farmers (59%), however, few (8.4%) were producing ginger while none was cultivating turmeric. Only 5% and 4% of the participants had earlier been trained on ginger and turmeric production respectively. There was an increase in mean knowledge score from 0.70 ±1.488 to 6.73±2.209 and 1.33±2.415 to 8.04±1.984 for ginger and turmeric production respectively after exposure to training. Likewise, post training knowledge mean score (5.77±2.177) was higher than pre training mean score (1.54±2.307) in economics of production of the two commodities. Results of the T-test reflects a significant difference in participants pre and post knowledge score in ginger (t = 21.98, p = 0.000) and turmeric (p = 21.664, p = 0.000) production, economics of production (t = 13.871, p = 0.000), processing (t = 19.563, p = 0.000) and overall (t =25.376, p = 0.000) along the value chain. Capacity building of horticultural stakeholders is indispensable for sustainable food security and health in this era of climate change.

Key words: Economic, youth involvement, value addition, value chain

INTRODUCTION

Ginger (*Zingiber officinale*) and Turmeric (*Curcuma longa*) are important spices both locally and globally (Amadi *et al*, 2018; Chidiebere and Ibe, 2018). They are well known at both local and international markets due to their numerous nutrition and health benefits. Ginger and Turmeric are important crops and farmers should be encouraged to invest in commercial production of both crops because of their potentials to improve health, income and economic levels of farmers (Chidiebere and Ibe, (2018, Amadi et al, 2018). Nigeria is the third largest producer of ginger in the world (VCA Ginger in Nigeria, 2020). The worth of ginger exported by Nigeria in 2016 was worth $8.2 million representing 9.6% of total world export (Workman, 2017). Nigeria ginger is highly rated in the international market due to its pungency and high rate of oleoresin oil. According to Amadi *et al*, 2018, Nigeria has potential in turmeric production considering the favourable soil and climatic conditions in the country. One of the difficulties facing Nigerian ginger sector is high post-harvest losses (VCA Ginger in Nigeria, 2020). Amadi *et al*, 2018 also stressed that a lot need to be done, especially in processing of turmeric to achieve food security. Thus to benefit maximally from ginger and turmeric, value addition is germane. In order to minimize post-harvest losses and ensure that food safety practices are adhere to, there is the need to build the capacity of interested youth, women and men along the value chain. Previous research efforts on Ginger and Turmeric are on economics of production and marketing (Sambo *et al* 2019, Chidiebere and Ibe, 2018). There is little information on effect of training on knowledge of stakeholders along the commodities value chain. The present study therefore described the socio economic characteristics of trainee and examine effect of training on participants' knowledge on ginger and turmeric along the value chain.

The specific objectives are:

i. To determine the socio economic characteristics of trainees
ii. Assess the effect of the training workshop on participants' knowledge

MATERIALS AND METHODS

The study was conducted at Saki zone of the Oyo State Agricultural Development Programme (ADP) in Oyo state. The zone was chosen due to the availability of favourable climatic conditions to support the growth of the selected spices. Two hundred and ten participants were contacted with the assistance of the Oyo state ADP. Selection cut across Saki west, Atisbo, Orelope, Kajola, Olorunsogo, Iwajowa, Orelope, Saki East, Saki west and Irepo communities under Saki zone of the ADP. Targeted beneficiaries were farmers' organization, women, youth and ADP staff. Participants were assessed and trained on technical knowledge on production, processing, nutrition and health benefits, record keeping as well as economics of ginger and turmeric. This was done to determine the gap and gain in knowledge before and after the training respectively. Data were collected from 100 respondents using interview schedule, however, 83 (83%) questionnaires that were found useful out of the 100 questionnaire prepared for the study were analyzed using both descriptive and inferential statistics.

RESULTS AND DISCUSSION

Socioeconomic Characteristics of Respondents

Most participants at the training workshop were male (65.1%) and married (83.1%). This is an indication that more men participated in the training workshop. Greater proportion of participants were within 50-59 years (30.7%) while majority (54.2%) having tertiary education. Most of the respondents have 1-10 members in their respective households (69.9%). Many (59%) were farmers but only 8.4% were producing ginger while none was cultivating turmeric. A considerable proportion (39.8%) of the producers had more than 20 years of farming experience and belong to farming association (60.2%). Only 5% and 4% of the participants had been trained on ginger and turmeric production before NIHORT training workshop (Table 1).

Pre and post knowledge assessment of participants

Considering the mean knowledge scores of participants before and after training, there was an increase in knowledge mean score from 0.70 ±1.488 to 6.73±2.209 and 1.33±2.415-8.04±1.984 for ginger and turmeric production respectively. Participants' knowledge mean score in value addition also reveal a change from 2.27±4.469 to 14.18±4.260. Likewise post training knowledge mean score (5.77±2.177) was higher than pre training mean score (1.54±2.307) in economics of production of the two commodities. The result indicated that the participants experienced a positive change in skill and knowledge after exposure to the training workshop. This could also be attributed to the fact that participants were involved in hands-on practical experience during the training exercise. Layade et al (2018) observed increase in knowledge score among participants after a training session on mango value chain among horticultural stakeholders.

T-test analysis of pre and post knowledge assessment in ginger and turmeric value chain

Results of the T-test reflects a significant difference in participants pre and post knowledge score in ginger production ($t = 21.98$, $p = 0.000$), turmeric production ($p = 21.664$, $p = 0.000$), economics of production of ginger and turmeric ($t = 13.871$, $p = 0.000$), processing of ginger and turmeric ($t = 19.563$, $p = 0.000$) and overall ($t = 25.376$, $p = 0.000$) along the value chain (Table 3). In a related study, Olajide-Taiwo et al, 2018 observed a significant difference in trainees' pre and post knowledge score after participating in training activities.

CONCLUSION AND RECOMMENDATION

Most participants were male, married, had tertiary education with 1-10 family members. Few participants were involved in ginger production while none was cultivating turmeric as at the time of the training workshop. Along the value chain, post knowledge assessment score was higher than the pre knowledge assessment score. Significant differences exited between pre and post knowledge mean score on the selected commodities along the value chain indicating that the training was beneficial to the participants. To ensure that training of participants translate to action that can lead to sustainable food security and health in the era of climate change, there is the need for follow up on participants for feedback as well as impact assessment in the nearest future.

ABSTRACT

Training needs is one of the crucial steps towards identifying the area of farmers' interest, design and development of curriculum that can best suit to the existing real conditions of farmers. Therefore, training is needed on garden for both the trainers, student and every farmers or individual involve in agriculture for efficient and effective improvement in agriculture and in knowledge on maintenance of gardens. Fifty students from each of the Senior Secondary School 2 students in the three adopted schools were randomly sampled to assess the students' sources of information on gardening and students' training needs areas in the school gardening activities. Results revealed that 62% have heard of school garden which is as a result of various intervention programs from NIHORT, while 38.0% were ignorant of the school garden probably because of lack of interest. However, Majority of the student (91.3%) were eager to be trained on horticultural school garden, while 8.7% were not interested in the training at all. The study concluded that training student on planting and harvesting of crops as well as livestock management in school/home garden will increase their interest in gardening from tender age; thereby sharing the knowledge from the training with their friends and families. This will increase gardening/agricultural practices in schools and homes in Nigeria. Hence, availability of adequate safe food for Nigerians.

Key words: Gardening, schools, adopted villages, training needs

INTRODUCTION

Agriculture is a key sector in Nigeria's economy and provides an important source of food and income to a large number of households, most of which are located in rural areas. Subsistence is the dominant agricultural management system in Nigeria, with most agricultural activities being carried out to produce food for household consumption and in some cases to sell at local markets or to neighbours. Production activities focus on the crop especially horticultural crops, livestock, fisheries sub-sectors and etc. Some farmers, mostly women grow small quantities of vegetables and fruits, mainly for household consumption, with small surpluses being sold in local markets. Some schools and home compounds are set up as gardening for raising horticultural crops and ensuring that children are involved in school and home gardening.

School gardening was coined out of home gardening (Gautam *et al*., 2002). Home gardening as a concept refers to the cultivation of small portion of land which may be at the back of a home or within a walking distance from home (Odebode, 2006). It is this concept of cultivation of land at the back of home or within a walking distance for the purpose of meeting multipurpose family and households needs. Home gardens is the intimate, multi-storey combination of various trees shrubs; annual and perennial and crops; herbs, spices, medicinal plants in association with fish and domestic animals around homestead on the same land unit, in a spatial arrangement or on a temporal sequence (Eyzaquirre and Linares, 2004; Kumar and Nair, 2004)

In Nigeria, great diversity exists in farmers' access to extension services, as well as the quality of services provided. To have an impactful and productive extension training services, the audience must be interested in the content of the training. This necessitates needs assessment evaluation before the training. Training needs is one of the crucial steps towards identifying the area of farmers' interest, design and development of curriculum that can best suit to the existing real conditions of farmers. Caffarela (2002) noted that a systematic process of farmers' training must include needs assessment, goal and objectives setting, organizing instructional methods and techniques, monitoring and evaluation.

Furthermore, training is needed on garden for both the trainers, student and every farmers or individual involve in agriculture for efficient and effective improvement in agriculture and in knowledge on maintenance of gardens (school and home garden). Meenambigai and Seetharaman (2003) asserted that training is the most singular factor affecting individuals' attitude, productivity, improvement, minimization of risks. So, adequate training is essential for farmers to acquire necessary knowledge and skills in different aspects of farming. It is therefore imperative that secondary school students are organized and given adequate training through agricultural extension to ensure that they are well informed and adequately skilled on gardening (both school and home gardening).

Objectives of the study were to:

- Identify the personal characteristics of the students
- Identify the students' sources of information on gardening in junior secondary school.
- Assess students' training needs areas in the school gardening activities.

MATERIALS AND METHODS

The study was carried out in Ibadan, Oyo state. The sampling involved a purposive selection of three adopted schools of National Horticultural Research Institute Ibadan: Baptist Grammar School, Idi-ishin, Oba Abass Aleshinloye Grammar School, Eleyele and Urban Day Secondary School Jericho. Fifty students from each of the Senior Secondary School 2 students in the three adopted school were randomly sampled for the study. Structured questionnaire was used to elicit information from the students. The total number of respondents sampled from the three schools was one hundred and fifty. Descriptive statistics such as frequencies and percentages were used to analyze the data collected.

RESULTS AND DISCUSSION

The respondents sex was male 57.3% and female 42.7%, there are more male than female in the senior students in the secondary school (Table 1). Thus there were more male in the study area. This finding was corroborated by (Nweke et al. (2002). About three quarter of them being 15-17 age bracket 76.7%. They are young, agile and still under the guide of parents /guardians. This implies that these students were still in their economic active age which could result in a positive effect on training. This result agrees with the findings of Kainga and Seiyebo (2012) who observed that the age has great influence on training because of their flexibility to new knowledge or ideas. Three schools were sampled to ascertain their knowledge in school garden and 62.0%. This is an indication that students have a good knowledge of what horticulture is and is not. Kettlewell and Henry, 2009) opined that prior knowledge acts as a lens through which we view and absorb new information. It is like knowing where one wants to go before the start of a journey. Individual goals and interest produce motivation, that is, a person is directed towards a particular activity which is aimed at accomplishing goals or exploring interest. This finding agrees with Gillie and Gillie (2003) who argued that making informed and considered career decisions has benefits which indicated that they have heard of school garden this may be as a result of various intervention programs from NIHORT while 38.0% were ignorant of the school garden probably because of lack of interest. However, Majority of the student (91.3%) were eager to be trained on horticultural school garden while 8.7% were not interested in the training at all. Garden training in this areas will increase their school income as asserted by Ajayi (2008). It is clear that training is an essential resource which will direct knowledge and skill toward production (Adesoji et al, 2006). This indicates that garden activities in the study area are still in need of training that has to be provided in order to boost their level of production and also increase their standard of living. In the school of more than half (59.3%) of the respondents there is school garden where they can practice what they would be trained on. Schools without garden (40.7%) can kick start their school garden after training. There is need for the training as most (39.3%) of the school garden are functioning. This may be as a result of lack of adequate knowledge of gardening activities. Although 55.3% of the respondents are involve in school garden activities. However, majority (90.7%) of the respondent are willingness to participate in school garden training.

Table 1: Personal Characteristics of selected secondary school student

Parameter	Frequency	Percent
SEX		
Male	86	57.3
Female	64	42.7
AGE		
12-14	18	12.1

Teachers	32	21.4	118	78.7
Young farmers club	78	52.0	72	48.0

Source: School survey, 2021

The students learn more in the school through their teachers. The student assesses information through their teachers (78.7%) and friends (68.7%). This implies that if a student is trained, he/she can share the information with friends and family (Table 2). Mass media (Television: 68.7%; Radio: 60.6%). This implies that adaptation strategy using teacher, friends, television and radio are likely produce more result because it is most prevalent source of information in the study area. This finding is consistent with that of Yekini (2010) who recognized that popularity of local radio stations stems from a sense of proximity with the listening community. Radio has proven useful in communicating agricultural technologies to farmers and garden activities with the objective of increasing agricultural production (Nwankwo and Orji, 2013) is also a good information source for the student with wider coverage. Bringing in practical agricultural training to the school where close to 80% information can be assessed by the student trough their teacher who can pass the information to the students under their tutelage is the most effective source of information of the respondents. There is need to strengthen in the young farmer's club (48%) in the secondary school in order to build the student interest in agriculture. The least mode of information assessment is through extension services 44.0%. Similarly, Mala (2012) observed that regular contact with extension agents lead to a significant knowledge gain by farmers. This is a cogent reason for this study to intensify on the Extension Services of research institute and other relevant agencies. Extension enables farmers to take up new innovations, to improve their production and income, and to protect the environment. However, to achieve optimum production in horticultural activities, smallholder farmers including students working in the school garden can benefit from tailored training as part of agricultural extension. (Table 3)

Table 3: Agricultural training needs of secondary school student

Training Need	Highly Needed		Moderate Needed		Not Needed	
	freq	%	Freq	%	Freq	%
Land clearing	96	64.0	30	20.0	24	16.0

Source: School survey, 2021

Training is acquisition of the best way of utilizing knowledge and skill (Sajeev and Singha, 2010; Training in these areas will increase their school income as asserted by Ajayi (2008). Assessment of the training of student on agricultural activities will give opportunity of handling the aspect of training intervention required by the audience. The student training needs on agricultural practices shows that planting 74.7%, livestock management 71.3%, Adeyemo and Onikoyi, (2012) reported that poultry production outnumbered other all forms of livestock production in Nigeria, this is because it requires less space and can be raised mainly on compounded rations which is available in animal feed store compared to other livestock. and harvesting (67.3%), rank high among the agricultural activities whose training are highly needed among secondary school students while harrowing 36.7% and ploughing 34.7% are moderately needed. This may be because of the small size land available for gardening in the school, which can be easily handled manually without the use of machineries. Training the students will put them through a process of acquisition of new skills, attitude and knowledge in the context of preparing for entry into a vocation presently and in future as this will increase their student interest in agriculture or improving productivity of their school or an organization (Rahman and Khatun, 2018). The training of the gardening activities will be done based on the need assessment will give room for effective training that requires a clear picture of how the trainees will need to use information after training in place of local practices i.e. their schools what they have adopted before or intending to adopt in their situation (Rahman and Khatun, 2018).

CONCLUSION

Training needs assessment is crucial for effective and impactful training that will increase knowledge, skills and translate to increase productivity. Training student on planting and harvesting of crops as well as livestock management in school/home garden will increase their interest in gardening/agriculture from tender age; they will also share the knowledge from the training with their friends and families. This will increase gardening/agricultural practices in schools and homes in Nigeria. Hence, availability of adequate safe food for Nigerians.

ABSTRACT

The study examined the socio-economic characteristics of Kola farmers' knowledge and its rehabilitation techniques practices in Edo State, Nigeria. Data were obtained using interview schedule, frequency, percentage, mean, graph, multinomial logistics, regression and standard deviation. The results showed a weak and poor extension services ranking (4.71%), with inadequate finances (4.07%), high cost of labour (3.88%), time consuming (3.55%), poor skills (3.03%) and pests and diseases (1.76%). However, Kola farmers should see Good Agricultural Practices (GAPs) and extension contact visits as best alternative to bridge the knowledge gap in increasing kola yield and farmers' income.

Key words: Knowledge, practises, rehabilitation and techniques.

INTRODUCTION

Kola nuts have been an important trade item in the West Africa region for many years. The kola nuts are valued in many cultures as a sign of friendship and peace and are consumed (broken) at reunions, during meetings, ceremonies and festivals. It is also the only stimulant allowed and consumed by religious faithful (Asogwa *et al.,* 2006). Kola is an important economic cash crop to a significant proportion of Nigeria population who are involved in kola farming, trading and industrial utilization. Nigeria currently produces 70% of world kola nut with an annual production of 200,000 metric tonnes of fresh nuts, mostly in the South West and surrounding boundary of South-South Nigeria.

The potential and importance of kola as a cash crop cannot be over emphasised due to its contribution to the economy of Nigeria GDP (Opeke, 1992). Due to increase in domestic market for kola arising from the expansion of sales of Cola beverages and other products containing kola nuts and the by- products, recent discoveries of their potential industrial uses has enhanced the market prospects for kola. Despite the huge success of Nigeria ranking in kola production in Africa, kola farmers' production still remains poor due to farmer's socio economic characteristics, old kola farm plantation that need Good Agricultural practices (GAPs), and the long gestation of maturity. The main objective of this study was to evaluate the socio economic characteristics of kola farmer's production, while the specific objectives examined the socio economic characteristics of kola farmers in the study area and examine the constraints faced by kola farmer's on rehabilitative techniques in study areas.

Hypotheses of the study

There is no significant relationship between the farmer's socio economic characteristics and their knowledge on kola farm rehabilitation technology.

There is no significant difference among the constraints faced by kola farmer's rehabilitation techniques.

MATERIALS AND METHODS

Study Area:

The research was conducted in Owan district Local Government of Edo State which comprises both Owan West and Owan East with the following communities namely; Uhonmora, Ozalla, Uzebba, Aviose, Opuje, Emai, Ojavun, Ikaho, Otuo and Iki. The communities were purposively selected because of its large numbers of kola farmers in the study areas. Data were obtained using interview schedule, descriptive, frequency, percentages, mean, graphs, multinomial logistic regression and standard deviation.

RESULTS AND DISCUSSION

The age distribution of kola farmers in the study area shows that majority of the respondents are aged 51 – 60) years old, while the least age of the respondents falls between less than 30 years of the respondents (Table 1) These findings indicate that farmers in the age bracket of 51 – 60 years old are very active in kola farming, since most of the kola farmers inherited their kola farms from their parents.

Table 1. Distribution of age of kola farmer's respondents

		Owan west		Owan East		Total	
		Freq	%	Freq	%	Freq	%
Age (categories)	>= 30	7	8.14	7	7.07	14	7.57
	31-40	12	13.95	8	8.08	20	10.81
	41-50	24	27.91	31	31.31	55	29.73
	51-60	28	32.56	33	33.33	61	32.97
	61-70	10	11.63	13	13.13	23	12.43
	>70	5	5.81	7	7.07	12	6.49
	Total	86	100.00	99	100.00	185	100.00

Source: Field survey, 2020

Educational level of respondents reveals that 46.49% has secondary education qualification, while 27.57% has primary education, 14.59% has tertiary education and the least has 11.35% with no formal education (Table 2). These findings imply that the educational status of respondents in the study area fall between average, and this can facilitate their adoption on their effectiveness on training.

Table 2. Respondents' education distribution

		Owan west		Owan East		Total	
		Freq	%	Freq	%	Freq	%
Education	No formal education	12	13.95	9	9.09	21	11.35
	Primary education	25	29.07	26	26.26	51	27.57
	Secondary education	35	40.70	51	51.52	86	46.49
	Tertiary education	14	16.28	13	13.13	27	14.59
	Total	86	100.00	99	100.00	185	100.00

Source: Field survey, 2020

Majority of the respondents falls between household size of 5-8 persons (51.35%), followed by 4 and below (32.43%), 9- 12 persons (10.27%) and the least of household size of respondents is 5.95% (Table 3).

Table 3. Household size of respondents of kola farmers

		Owan west		Owan East		Total	
		Freq	%	Freq	%	Freq	%
Household size (range)	4 & below	31	36.05	29	29.29	60	32.43
	5-8	42	48.84	53	53.54	95	51.35
	9-12	6	6.98	13	13.13	19	10.27
	>12	7	8.14	4	4.04	11	5.95
	Total	86	100.00	99	100.00	185	100.00

Source: Field survey, 2020

Marital status of respondents shows that majority (78.92%) of respondents are married, while 4.32% were single, 2.70% divorced and 14.05% are widower. This implies that most of the respondents who were married were involved on farming activities. This also indicates the family cohesion has great influence in improving family supports and livelihood of the respondents.

Table 4. Marital status of kola farmers' respondents

		Owan west		Owan East		Total	
		Freq	%	Freq	%	Freq	%
Marital Status	Married	68	79.07	78	78.79	146	78.92
	Single	6	6.98	2	2.02	8	4.32
	Divorced	2	2.33	3	3.03	5	2.70
	Widower	10	11.63	16	16.16	26	14.05
	Total	86	100.00	99	100.00	185	100.00

Source: Field survey, 2020

Table 5 shows the sex distribution of respondents which indicate the male respondents has (62.70%) than the female with (37.30%). This result confirmed the findings of Ele et al; (2013), Shaibu et al; (2017); Olaoye et al; (2011) which reported that male counterpart involves more in Agricultural activities in Nigeria than female counterpart.

Table 5. Gender distribution of kola farmers

		Owan west		Owan East		Total	
		Freq	%	Freq	%	Freq	%
Gender	FemaleMale	34	39.53	35	35.35	69	37.30
	Total	52	60.47	64	64.65	116	62.70
		86	100.00	99	100.00	185	100.00

Source: Field survey, 2020

Membership of association has a greater influence on agricultural activities of which 81.62% of the respondent farmers belong to one association or the others, while 18.38% do not belong nor has interest in joining any membership of association (Table 6). This implies that low membership can lead to low response on participation on training adoption of new technology.

Table 6. Membership of respondents of kola farmers' association

		Owan west		Owan East		Total	
		Freq	%	Freq	%	Freq	%
Membership of association (dummy)	Non- member	18	20.93	16	16.16	34	18.38
	Member	68	79.07	83	83.84	151	81.62
	Total	86	100.00	99	100.00	185	100.00

Source: Field survey, 2020

Table 7 shows the significant of respondent's knowledge of different rehabilitation technology. This finding further revealed that fertilizer application is necessary after coppicing with total mean of significant of (4.54%), followed by coppicing (4.51%), Cutting of old moribund of kola tree (4.32%), Removal of chupon (4.30%), Fertilizer application (4.27%), Use of motor saw for coppicing operation (4.17%), Pruning (4.08%), Application of fungicides/insecticides (4.07%), Coppicing of kola tree above 30-60cm from ground level (4.03%), Ring weeding (3.99%), and painting stump after coppicing prevent diseases with less of significant mean of (3.98%) respectively. This finding prove or shows that fertilizer application shows more significant preference among all the rehabilitation technology on knowledge and least preference on painting of coppiced kola trees.

Table 7. Knowledge of kola farm rehabilitation technology practice

Technologies	Owan west		Owan East		Total	
	Mean	SD	Mean	SD	Mean	SD
Fertilizer is necessary after coppicing	4.43	0.7	4.63	0.5	4.54	0.6
Coppicing is a best practices KFRT	4.47	0.6	4.56	0.6	4.51	0.6
Cutting of old moribund kola trees is best form of rehabilitation	4.42	0.5	4.23	0.5	4.32	0.5
Removal of chupon is best practices of kola rehabilitation	4.29	0.5	4.31	0.5	4.30	0.5
Fertilizer rehabilitation boost kola rehabilitation	4,28	0.5	4.26	0.6	4.27	0.5
Motor saw is the best tools to used to carry out coppicing operation	4.19	0.4	4.15	0.4	4.17	0.4
Pruning can be done once or twice a year	4.16	0.4	44.00	0.3	4.08	0.3
Application of fungicides and insecticides is good for kola rehabilitation	4.08	0.4	4.06	0.3	4.07	0.4
Coppicing kola tree above ground level of 30cm to 60cm is good for kola rehabilitation	4.01	0.3	4.04	0.3	4.03	0.3
Ring weeding should be done 2 to 3 times annually	4.01	0.3	3.98	0.4	3.99	0.4
Painting surface kola tree prevent diseases	3.99	0.4	3.98	0.4	3.98	0.4

Table 8: shows the constraints limiting respondent's adoption on kola rehabilitation technologies. Findings of the results shows the possible constraints facing the adoption constraints to kola rehabilitation technologies. The pooled results reveal all the constraints listed in the above serious based on mean benchmark of 2.50. The major constraints include lack of week and poor extension services (mean = 296), inadequate finance (mean =3.05), high cost of labour (mean =296), time consuming (mean 2.82), lack of knowledge/ poor skills (mean =2.63) and lack of pests and diseases (mean =2.01). The weak and poor extension services, as major constraints may be as a result of the fact that respondents do not have sound formal education, since their educational level still fall below average of (46.49%).

Table 8. Constraints limiting respondent's adoption on kola rehabilitation technologies

Constraints	Owan west		Owan East		Total	
	Mean*	SD	Mean*	SD	Mean*	SD
Weak and poor extension services	3.44	0.5	3.38	0.5	3.41	0.5
Inadequate finance	3.05	0.6	3.05	0.6	3.05	0.6
High cost of labour	2.98	0.5	2.95	0.5	2.95	0.5

Table 10. Constraints to farmer's adoption on kola farm rehabilitation techniques

Constraints	**Mean rank**
Pests & Diseases	1.76
Lack of knowledge & skills	3.03
Time consuming	3.55
High cost of labour	3.88
Inadequate finance	4.07
Weak and poor extension services	4.71

Source: field survey, 2020

The result of hypothesis test on the significant difference on constraints to farmer's adoption of kola farms rehabilitation techniques. Statistically, the results have shown the weak and poor extension services rank the highest with mean (4.71), followed by inadequate finance (4.07), high cost of labour (3.88%), time consuming (3.55%), poor skills (3.03) and pests and diseases with (1.76%) respectively. These results indicate that extension services need to be intensify adoption techniques to kola farmers at the right time through the Ministry of Agriculture and Research extension outreach centres in the state; since extension information is part of educational baseline for adoption of new technology.

CONCLUSION AND RECOMMENDATION

From the findings, kola farmers' knowledge on kola farm rehabilitation technology (KFRT) reveals that they really have knowledge and practical skills on the Good Agricultural practices (GAPs), but find it difficult to continue on the practices despite its impact on both yield and finance on the kola farmers. Majority of respondents see poor extension services, time, finance, labour, poor skills, pests and diseases, low cooperation of kola farmers that ought to connect them fully with government in term of support compared to other tree/cash crops such as; Cocoa, Coffee, Cashew and groundnuts among others. This would have contributed to effective adoption of the technology that was later discontinue due to constraints been faced by the kola farmers in the study area. There is needed to form a formidable kola farmers' association (KFA) in the study area of Edo State. This will also expose the kola farmers to different measures of awareness from (CRIN) and various groups within the association in other to assist the farmers to access both information and credit facilities that will enhance their production and their standard of living. Also, there is need for sensitization and mobilization of relevant stakeholders in kola industry to established Farmers – Field Schools that will bring kola farmers from different locations to understudy a specific

ISSN: 2814-0508

technology using their knowledge so as to re-activate old kola moribund plantations from extinction. Indigenous knowledge system should be incorporated in the new modern teaching of kola rehabilitation technology practices that will enhance low kola farmers' participation for easy understanding and adoption of the technology. Finally, Kola farmers should see Good Agricultural practices (GAPs) as the sole alternative with knowledge application as the only way to increase kola yield and better income.

ABSTRACT

Excursion tour is a vital educational tool that complements classroom knowledge. The study assessed knowledge of tertiary Institution students on the purpose of excursion tour. One of the tertiary Institutions that came for excursion tour to National Horticultural Research Institute in 2021 were purposively selected due to their large number. Random sampling technique was used to select 30% out of the 319 students. Questionnaire was used to elicit information and data were analyzed using frequency and percentages. Majority (58.9%) of the students were between 21-25yrs, 71.1% female, 95.6% were interested in horticulture as a career. Majority (87.8%) agreed that excursion is an educational tool, increases students' knowledge (93.3%), helps to meet new people (85.6%), helps students to learn more and inspired by what they see (80.0%). Most of the respondents (74.4%) disagree that excursion does not help to develop cooperative attitude and does not assist in development of initiatives and leadership skills (68.9%). The Institute was rated excellent and very good by 51.1% and 22.2% respondents respectively. The students are quite knowledgeable on the importance of excursion. Relevant organizations should continue to support excursion on a regular basis to improve academic performance and promote students' interest in horticulture for sustainable food security and health in the era of climate change.

Key words: Excursion, knowledge, Tertiary Institutions, NIHORT

INTRODUCTION

One type of informal learning experience, more commonly known as educational excursion, is valued by many educators for its potency to increase interest and enhance information that is being taught inside the classroom (Hudak, 2003). Educational excursion is a progressive method of learning by which the student goes through the necessary learning experiences under the leadership and guidance of the teacher (Shakil et al., 2011). Carolyn (2009) admit that taking pupils outside the comfort of the classroom can be a daunting step for some teachers, but admits strongly that field trips provide unique opportunities to apply learning to the real world. Excursion tour is a journey into the land of knowledge for the purpose of acquiring practical knowledge and skill for a specified operation or occupation (Nwakor, 2006). It is helpful in physical, mental, social and emotional development of students.

Excursion visit has the tendency to complement classroom learning and impart practical knowledge of students. Excursion by students is a common routine that is embedded in the curriculum of most schools. In pursuit of better and satisfactory student performance in agricultural science in Secondary Schools examination in Nigeria, West African Examination Council (2006) recommended students' visitations to well established government and private experimental and commercial farms, agricultural research institutes and other institutions related to agriculture. It is very essential to find out whether students are knowledgeable about the purpose of excursion. The study assessed excursion knowledge among students on educational tour to National Horticultural Research Institute (NIHORT).

The specific objectives were to:

i. determine the personal characteristics of students
ii. assess students' knowledge about excursion
iii. ascertain students feed-back after excursion

MATERIALS AND METHODS

The 300 Level students of one of the tertiary Institutions in Nigeria that came for excursion tour to National Horticultural Research Institute (NIHORT) in 2021 were purposively selected due to their large number. Three hundred and nineteen students from the school came in three batches of 110, 150 and 130 within a month. Random sampling technique was used to select 30% of the students from each of the group and questionnaire was administered to elicit information from them. Only 90 questionnaires that were properly filled were analyzed using frequency and percentages.

RESULTS AND DISCUSSION

Personal Characteristics of the Respondents

Majority (58.9%) of the students were between 21-25yrs, 71.1% were female and 57.8% major in Biology. Majority (95.6%) were interested in horticulture, 55.6% indicated interest in horticulture as a career choice while only 32.3% had previously visited agricultural organization (Table 1). More female than male could be an indication that more female enrolled in the selected school than boys. Educational excursion is a good way to create interest about a subject or a course, the educational visit may result in students' interest in horticulture. Horticulture is a unique field due to the arrays of crops within its scope. This could be one of the reasons why majority of the student indicated interest and significant proportion also affirmed readiness to choose horticulture as a career. This could probably reduce the erroneous believe by some people about horticulture as a field dealing with ornamental plants alone.

Table 1: Personal Characteristics of the Respondents

	Variable	Frequency	Percentage (%)
Age	16-20	22	24.4
	21-25	53	58.9
	26-35	15	15.5
	Sex		
	Male	26	28.9
	Female	64	71.1
Course of study	Integrated/biology	8	8.9
	Biology/chemistry	19	21.1
	Biology	52	57.8
	Integrated science/Computer	2	2.2
Students interest	Interest in horticulture	86	95.6
	Interest in the excursion	86	95.6
	Career choice in horticulture	50	55.6
	Previous visit to agricultural organization	29	32.3

Respondents Knowledge about Excursion

Majority (87.8%) of the respondents agreed that excursion is an educational tool, increases students' knowledge (93.3%), helps to meet new people (85.6%) and helps students to learn more and inspired by what they see (80%). On the other hand, 84.4% and 74.4% disagreed that excursion helps in the development of creative faculties and does not help to develop cooperative attitude respectively, while 68.9% disagreed that it does not assist in development of initiatives and leadership skills (68.9%) (Table 3). On the other hand, respondents disagree that excursion does not help to develop cooperative attitude (74.4%) and development of initiatives and leadership skills (68.9%) respectively (Table 3). The results indicated that the students are knowledgeable about the significance of excursion. This is in line with the work of Carolyn (2009), who admits strongly that field trips provide unique opportunities to apply learning to the real world. It buttresses the work of Nwakor (2006) that excursion is a journey into the land of knowledge for the purpose of acquiring practical knowledge and skill for a specified operation or occupation.

Distribution of Respondents on Feedback on Excursion

Table 4 shows that majority (77.6%) agreed they would like to visit NIHORT again for their excursion. The Institute was rated excellent, very good and good by 51.1%, 22.2%, 6.7% respondents respectively while staff of the institute that attended to them were also rated as excellent, very good and good by 48.9%, 20.0%, 6.7% respondents respectively. Majority (70.0%) affirmed that their expectations on the excursion was met. This is an indication that the staff that attended to the students are competent and skillful in passing appropriate information across to the audience. Exposure of students to the arrays of technologies generated in the Institute and receptive environment may also boost the interest of students in revisiting the Institute in the nearest future.

Table 3: Distribution of the Respondents based on their Knowledge about Excursion

S/N	Statement	Agreed freq. (%)	Disagreed freq. (%)	I don't know freq. (%)
1.	Excursion as an exciting education experience	79 (87.8)	6 (6.7)	5(5.6)
2.	Increase in students' knowledge	84 (93.3)	3(3.3)	3(3.3)
3.	Horticulture does not increase desires to try new things	9 (10.0)	79 (87.8)	2(2.2)
4.	It creates chance to meet new people	77 (85.6)	6(6.7)	2(2.2)
5.	Development of creative faculties	9 (10.0)	76(84.4)	3(3.3)
6.	Proper utilization of leisure	16(17.8)	62 (68.9)	3(3.3)
7.	It does not help in developing cooperative attitude	10 (11.1)	67 (74.4)	7(7.8)
8.	It does not assist in development of initiative and leadership skills	20(22.2)	62(68.9)	3(3.3)
9.	Students learn more and get inspired by what they see	72(80.0)	8(8.9)	-
10.	It provides opportunity for development of aesthetic sense	74(82.2)	3(3.3)	-

Source: field survey, 2021

Table 4: Respondents feed-back

Variable	Frequency	Percentage (%)
Willingness to visit NIHORT on another excursion	70	77.85
NIHORT rating by students		
Excellent	44	48.9
Very good	18	20.0
Good	6	6.7
Missing system	22	24.4
Staff rating by students		
Excellent	46	51.1
Very good	20	22.2
Good	6	6.7
Poor	1	1.1
Missing system	17	18.9
Expectation from excursion met	63	70.0

Source: field survey, 2021

CONCLUSION AND RECOMMENDATION

The students are quite knowledgeable on the importance of excursion, interested in horticulture and gave a positive feed-back about NIHORT after the excursion visit. More excursion should be carried out by educational Institutions. Relevant organizations should continue to support practical knowledge impartation among students by allowing students to come for excursion on a regular basis, this is to improve academic performance and promote students' interest horticulture for sustainable food security and health in era of climate change

ABSTRACT

Government intervention is essential for achieving rapid economic growth on agriculture. Cocoa improvement practices such as cocoa rehabilitation programme is essential for increase yield and improvement of social economic status of peasant farmers. Therefore, the attitude of cocoa farmers to cocoa rehabilitation in southern Nigeria was investigated. 300 cocoa farmers were sampled through a multistage sampling procedure. Data obtained were described using frequency and percentage, and analyzed using chi-square at p≤ 0.05. Results revealed 12.0% of the farmers are non-adopter, 21.0% adopted only one technique while 67.0% of the farmers adopted at least two of the technique. Attitudes such as training is important in cocoa rehabilitation {$\overline{X}$ =4.69}, cocoa rehabilitation reduces pests attacks {$\overline{X}$ =4.54} and cocoa rehabilitation is a solution to low yield {$\overline{X}$ =4.49} showed a favorable attitude. While attitudes such as cocoa rehabilitation does not promote cocoa beans yield {$\overline{X}$ =1.77}, and cocoa rehabilitation does not improve moribund cocoa trees performance {$\overline{X}$ =1.30} revealed unfavorable attitude. However, the hypothesis showed a significant relationship between some selected socio-economic characteristics and the attitude of cocoa farmers in the study area. These variables include, member of organization (0.674), House hold size (0.541), source of information (0.624) and number of cocoa farms acquired (0.521). The study concluded that cocoa farmers have both positive and negative pre-disposed attitudes to cocoa rehabilitation techniques used in the study area.

Key words: attitude, cocoa farmers, economic growth.

INTRODUCTION

Cocoa is a commodity crop relevant to most developing economy as it's produced by more than fifty developing countries across Asian, Africa, and Latin America (Ogunleye and Oladeji, 2007). It is a perennial tree crop grown in tropical climate, native of the Americas but which are now widely cultivated in West Africa. Studies revealed that about 5-6 million cocoa farmers exist worldwide, while 40-50 million people depend on cocoa for their livelihood (Adebiyi, 2020). Obviously, Nigeria was the second leading producer of cocoa in the world in 1965 but due to a combination of factors such as ageing of cocoa trees, ageing cocoa farmers (Adebiyi and Okunlola, 2009) and inadequate fund to acquire inputs (Sanusi and Oluyole, 2006). These aforementioned predicaments made cocoa production dwindling over time and Nigeria is currently the fourth world producer which is 367,000 tonnes after Cote d'Ivoire, Ghana and Indonesia (World Atlas, 2018).

The need to increase cocoa beans yield becomes paramount as Nigerian Government and the World Bank embarked on Cocoa improvement projects such as promotion of adoption of cocoa rehabilitation techniques which commence in 1999 under National Cocoa Development committee with the objective of rehabilitation of old and moribund cocoa trees in all 14 Cocoa producing states. This has yielded positive results of cocoa farmers have adopted various cocoa rehabilitation techniques transferred to them.

Cocoa rehabilitation techniques were considered to be the restoration of the yields to the peak level by the systematic replacement of inferior trees (Adebiyi *et al*., 2018. It can also be described as the process whereby unproductive cocoa farms or plantations can be made productive by extending the economic life of the trees through replacement of the old trees with improved younger cocoa tree (CRIN, 2001). Sequel to the above, this study was designed to determine attitude of cocoa farmers toward the practice of cocoa rehabilitation techniques and how it affects their participation in the scheme.

Hypothesis of the study

There is no significant relationship between some selected socio-economic characteristics of the respondents and their attitude towards cocoa rehabilitation techniques

MATERIALS AND METHODS

Smallholder cocoa farmers in Southern Nigeria were considered for this study. A multi-stage sampling procedure was used for the selection of respondents. From 10 cocoa producing states in Southern Nigeria; Ondo, Cross-Rivers and Oyo States were purposely selected because of their level of involvement in the Federal Government Cocoa Rehabilitation Programme. This was followed by purposive selection of two local governments and two communities where farmer's organizations participated in cocoa intervention programme. Finally, 25 small holder cocoa farmers were randomly selected using table of random numbers among the farmers in any of cocoa group they belong such as Cocoa Farmers Association of Nigeria and Cocoa Association of Nigeria. Thus a total of 300 respondents were selected and interviewed in this study. Structured interview schedule was used to collect data for the study. Frequency counts and percentages were used to describe the data while Pearson Product Moment Correlation was used to test the relationship between the attitude of cocoa farmers and their socio-economic characteristics. Attitude of cocoa farmers toward rehabilitation techniques was depended variable and was measured on a 5-poits Likert type scale.

RESULTS AND DISCUSSION

The ability of cocoa farmers to practice cocoa rehabilitation techniques introduced to them will determine the volume of cocoa production. Figure 1 shows 88.0% practiced cocoa rehabilitation techniques as few (12%) of the respondents did not adopt any of the techniques.

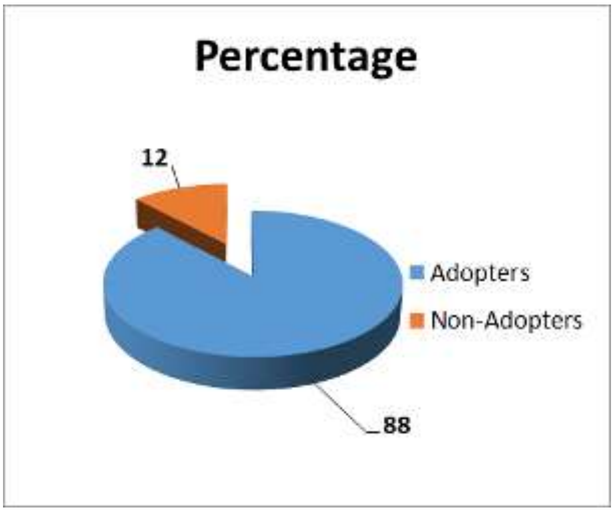

Figure 1: Distribution according to adoption

Multiple responses Source: Field Survey, 2017

The distribution of respondents by household size as shown in figure 2 reveals that some 49.9% of the respondents had household size of 1 - 5 persons, 47.0% of the respondents had household size of 6 - 10 persons while (3.3% and 0.3%) of the respondents had household size of 11 - 15 and greater or equal to 16 persons respectively. The mean household was 5 persons; this implies that the majority of the respondents have a moderate household size which could lead to access to farm labour (Oluyole, etal; 2013) stated that the larger the household size, the more family labour available for agricultural production.

ISSN: 2814-0508

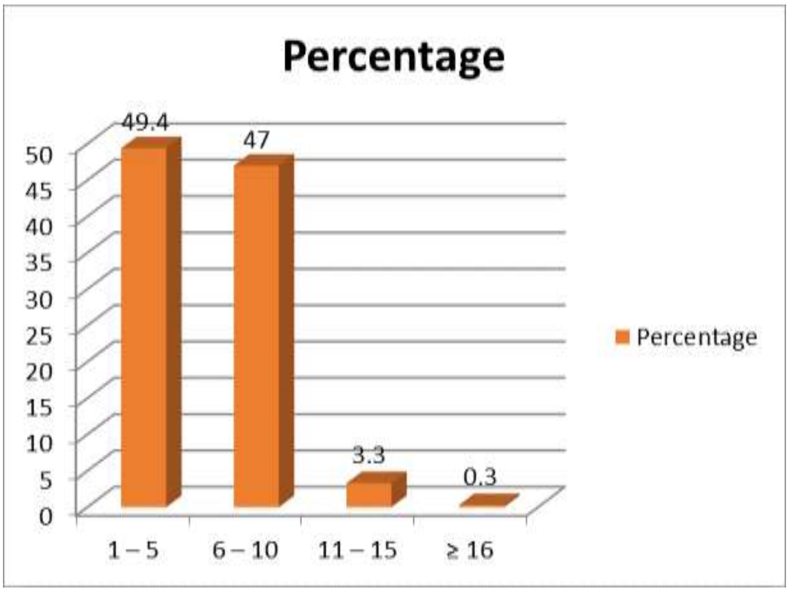

Figure 2: Distribution of the Respondents according to their household size

Mean = 5, Source: Field Survey, 2017

From Figure 3, the mean cocoa farms acquired were 3.3. The finding shows that, more than half (54.0%) of cocoa farmer acquired more than three cocoa farms, while 46.0% of the respondents claimed they have between one and two cocoa farms. This showed that apart from the cocoa farms the respondents acquired through inheritance which is too small to make the ends meet, some of them acquired more cocoa farms through purchased, leased, rent and share cropping. Adebiyi *et al.* (2013) supported that land fragmentation has made many cocoa farmers who view farming a career option to acquire more farms in addition to the one inherited from their father.

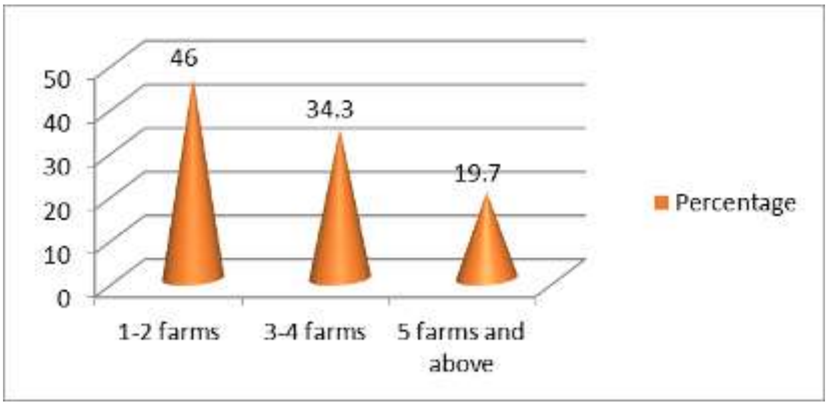

Figure 3: Distribution according to the number of cocoa farms acquired

Mean = 3.3. Source: Field Survey, 2017

Table 1 shows the distribution of respondents according to their membership in social group. The findings revealed that majority of the farmers (87.3%) were participants of social groups, it was also revealed that 51.3% were ordinary member, 36% of them were executive member, while, few (12.7%) of them were not member of social group. The implication is that farmers will be informed of new innovations introduced to their community. This agrees with the findings of Adebiyi *et al.* (2018) who discovered that being a member of group has a positive and significant relationship with adoption of new technology.

Table 1: Distribution of the Respondents according to membership of social group

Membership	Frequency	Percentage (%)
Non- Membership	38	12.7
Ordinary member	154	51.3
Member of executive	108	36
Total	300	100

Source: Field Survey: 2017

Table 2 revealed that State, Ministry of Agriculture (77%), Research Institutions (70.7%) and Cocoa Association of Nigeria/Cocoa Farmers Association of Nigeria (CAN/CFAN) (66%) were the most frequent source of information on planting under old cocoa trees as claimed by the respondents, Input Agency (60%), Radio/TV (59.7%), Extension Agent (53.3%), Friend/Neighbours (51.7%) and Non-Governmental Organization (NGO) (48.3%) were also sources of information on planting under old cocoa trees. This is in line with assertion of Akinnagbe and Ajayi (2012) on assessment of farmers' benefits derived from Olam Organization's Sustainable Cocoa Production extension activities in Ondo State, those cocoa farmers have improved knowledge and skill acquisition in their production as well as economics gains in terms of yield and income.

The Table further reveals that State Ministry of Agriculture (69.7%), Radio/TV (69%) and CAN/CFAN (63.7%) were the major sources of information on gapping up to cocoa farmers. However, the State Ministry of Agriculture (83.7%) and Research Institution (74.3%) are the major sources of information on coppicing. Information is germane to adoption as the medium and source determines the sustainability of any innovation introduced to farmers. Farmers depend on information that would help them to solve their production problems. This supports the findings of Famuyiwa *et al*. (2014) who found that innovative nature of some technologies affects its movement. Okunlola and Akinwalere (2019) also affirmed that source of information influence adoption of improved techniques in tree crop management.

Table 2: Respondents' sources of information on cocoa rehabilitation techniques

Multiple responses
Source: Field Survey, 2017

Table 3 reveals that the respondents have both positive and negative pre-disposition towards the practice of cocoa rehabilitation techniques. The respondents were positive pre-disposed to attitudes such as rehabilitation had promoted yield of cocoa trees ($\overline{X}$ = 4.38), adoption of cocoa rehabilitation enhanced my standard of living ($\overline{X}$ = 4.30), cocoa rehabilitation increased yield of cocoa trees ($\overline{X}$ = 4.38), reduced pest attack on cocoa farms ($\overline{X}$ = 4.54), rehabilitation is a solution to low yield ($\overline{X}$ = 4.49), training is important in cocoa rehabilitation techniques ($\overline{X}$ = 4.69), rehabilitation improves moribund cocoa trees ($\overline{X}$ = 4.44).

Inversely, respondents were negatively pre-disposed to attitude such as rehabilitation does not promote cocoa bean yield ($\overline{X}$ = 1.77) adoption of rehabilitation has not enhance my income ($\overline{X}$ = 1.55), rehabilitation is complex to practice ($\overline{X}$ = 1.59), rehabilitation is not a solution to reduction in output ($\overline{X}$ = 1.47). These attitudes have negative pre-disposition and were all categorized as

ISSN: 2814-0508

unfavourable attitude. The negative attitude towards cocoa rehabilitation techniques could be traced to low awareness, inadequate information, unavailability of planting materials and chemical inputs required in cocoa rehabilitation techniques. This is in consonance with Bisanda et al. (1998), who identified lack of knowledge and collateral as major constraints to obtain credit.

Table 3: Distribution of respondents according to their attitude about cocoa rehabilitation techniques

Cocoa Rehabilitation Techniques	Mean	Remark
Training is important in cocoa rehabilitation techniques (p)	4.69	Favourable
Cocoa rehabilitation reduces pests attack on my farm	4.54	Favourable
Cocoa rehabilitation is a solution to low yield of my cocoa farm (p)	4.49	Favourable
Cocoa rehabilitation is not difficult to practice (p)	4.49	Favourable
Cocoa rehabilitation has increased yield of my cocoa tree (p)	4.48	Favourable
Cocoa rehabilitation improves moribund cocoa trees in my farm (p)	4.44	Favourable
Cocoa rehabilitation has promoted cocoa beans yield (p)	4.38	Favourable
Cocoa rehabilitation promotes farm sanitation (p)	4.33	Favourable
Cocoa rehabilitation encourages management practices in my farm (p)	4.32	Favourable
Adoption of cocoa rehabilitation has enhanced my standard of living (p)	4.30	Favourable
Cocoa rehabilitation does not promote cocoa bean yield (N)	1.77	Unfavourable
Cocoa rehabilitation does not promote farm sanitation (N)	1.62	Unfavourable
Rehabilitation is complex to practice (N)	1.59	Unfavourable
Adoption of cocoa rehabilitation has not enhanced my standard of living (N)	1.55	Unfavourable
Cocoa rehabilitation does not reduce pest and diseases attack (N)	1.53	Unfavourable
Cocoa rehabilitation is difficult to promote (N)	1.49	Unfavourable
Cocoa rehabilitation is not a solution to reduction in cocoa output (N)	1.47	Unfavourable
Training is not important in capacity building (N)	1.47	Unfavourable
Cocoa rehabilitation does not encourage soil management practices (N)	1.43	Unfavourable
Cocoa rehabilitation does not improve moribund cocoa trees’s performance (N)	1.30	Unfavourable

Grand Mean = 2.98, High attitude ≥ grand mean = Favourable., Low attitude < grand mean = Unfavourable.
Source: Field Survey, 2017.

Table 4 revealed that membership of organization (r=0.674; p= 0.05) had the highest correlation coefficient with attitude of cocoa farmers toward rehabilitation techniques. The indication is that various organizations farmers belonged create awareness about cocoa rehabilitation programme and this is capable of stimulating their interest to participate in the programme.

There was a positive (r=0.624; p 0.05) and significant relationship between the farmers’ attitude and source of information. This implies that information available to cocoa farmers determines their level of participation. However, household size (r=0.541; p 0.05), and number of cocoa farm acquired (r=0.521; p 0.05) shows a positive and significant relationship with attitude of farmers toward cocoa rehabilitation.

Table 4: Relationship between some selected socio-economic characteristics of the respondents and their attitude toward cocoa rehabilitation techniques (n=300)

Variable	r- value	Decision
Member of organization	0.674*	Significant
House hold size	0.541*	Significant
Number of cocoa farm acquired	0.521*	Significant
Source of information	0.624*	Significant

*Significant at 0.05 levels
Source: Field Survey, 2017.

CONCLUSION

Cocoa rehabilitation which is an intervention programme of federal government to rejuvenate moribund cocoa farms has brought about increase in cocoa beans yield. However, there is need to consider positive attitude exhibited by the respondents in order to enhance participation in the programme. The favorable attitude revealed in this study revealed that, cocoa rehabilitation techniques practiced by cocoa farmers has brought about increase in their farm yield which results to the promotion of their socio economic status. Based on this findings, it is recommended that various stakeholders in cocoa industry should be encouraged to work together with cocoa farmers in order to solve farmers' problem in a more integrated and holistic approach.

ABSTRACT

Assessment of adoption of improved agricultural practices among home gardeners at neighborhood communities of National Horticultural Research Institute (NIHORT), Mbato, Okigwe Imo state was conducted in 2018. Combination of purposive and multi-stage random sampling techniques was used to select 64 farmers as sample size. Primary data were collected using structured questionnaire and oral interviews and analyzed with both descriptive and inferential statistical tools such as percentage, frequency table and 4- point Lickert scale. Result of data analysis shows that greater number of females (51.6%) practiced home garden activities than males (48.4%), the farmers had average age of 39 years, and average annual income was about N38,000.00, from home garden activities only. Meanwhile, all the farmers were aware of all the examined improved agricultural practices such as use of irrigation, crop rotation, fertilizer, pesticide and herbicide. With the exception of vertical farming and use of drones, however, use of manual irrigation, crop rotation, fertilizer and improved seeds was outstanding. While, some notable factors such as inadequate finance, and inadequate or lack of access to loan, significantly constrained adoption of improved agricultural practices in the area. It was therefore recommended that both state and local government as well as nongovernmental organization should offer farmers soft loan to enable them meet up with cost of adequate adoption of improved agricultural practices; also, NIHORT Mbato, local and state government should have sent adequate trained extension agents to the area, to intimate the gardeners on the current needs of improved agricultural practices.

Key words: awareness, adoption, improved agricultural practices, home garden

INTRODUCTION

Globally, agricultural productions have shifted from conventional and traditional farm practices to more diversifying and market oriented crops production. The need for fruit and vegetables production has been tremendously recommended in every part of the world (FAO, 2009). In the recent times, people growing both staple and non-staple crops within their surroundings have increased significantly. Home garden production is a wonderful aspects of agriculture that concerns with the cultivation of multipurpose and multi-storied trees and crops combined with animal husbandry around a homestead (Galhena, 2013). According to Uzokwe, *et al. (*2016) home gardens are of vital importance for the socio-economic development of subsistent and resource poor communities. It is an important source of supplementary income in the family (Adeoye *et al*., 2018). It is a sustainable agro system that meets various households needs such as food, medicine, ornamental purposes among others (Oritz-sanchez *et al*, 2015). According to FAO (2006), some vegetables and fruit varieties are grown in traditional gardens which lack improved know-how and depend on limited means for their upkeep. However, increased home garden production could play an important role of reducing reliance on food assistance and imports, and enhancing overall agricultural development (Hailu, 2008). Increased vegetables and fruit cultivation has been enhanced by the use of modern agricultural technologies. Though, traditional knowledge of farming is mainly utilized in home garden practices in the study area, the importance of improved agricultural production technologies in achieving sustainable increases in food production cannot be overemphasized. A good example for Africa to leverage on is the green revolution model in Asia and Latin America where significant economic growth has been achieved through the introduction and adoption of improved agricultural production technologies, mainly improved seeds, irrigation, fertilizers, pesticides, herbicide and farm arrangement (Hailu, 2008). Farmers are currently replacing their traditional crop cultivars with the new innovations including the improved varieties, in many cases with hybrid varieties (Eisses and Chaikam, 2002). By extension crop that provide higher economic returns, thus provide better livelihood opportunities. There is little or no information on the awareness and adoption of improved agricultural technologies in home garden practices in the study area, hence the objective of the study to assess the adoption of improved agricultural practices among home gardeners. Specifically, the study tends to; describe the socio-economic characteristics of the home gardeners, ascertain whether the farmers are aware of new agricultural practices, determine the level of adoption of improved agricultural practices and identify factors militating against adoption.

MATERIALS AND METHODS

The study was carried out in the neighbourhood communities of National Horticultural Research Institute (NIHORT), Mbato, Outstation, Okigwe local government area of Imo state, Nigeria in 2018. Five communities (Aku, Agbobu, Umulolo, Umuowa-ibu and Okigwe urban) that surround the Institute were surveyed. Okigwe is the third largest city, after Orlu and Owerri. The local government lies between $5^0 30^0$N to $5^0 57^0$N and $7^0 40^0$E to $7^0 55^0$E with population of 132,237(2005 census). Okigwe has a land mass of 1,824km^2 and less than 13km distance from Abia State University, Uturu. The people of Okigwe cultivate crops such as cucumber, watermelon, cassava, yam, maize, garden egg, telfairia, cocoyam, orange, plantain, etc. Combination of purposive and multi-stage random sampling techniques was used to select 64 farmers as sample size for the study. Primary data were collected using structured questionnaire from the sampled farmers.

RESULTS AND DISCUSSION

Result of data analysis in table 1 shows that greater number of females (51.6%) practiced home garden activities than males (48.4%) in the area. This is in line with the findings of Kabir *et al.* (2008) that women are mostly involved in home garden production and management-related activities. Increased involvement of women in a broad range of home garden production and management activities is not only beneficial for sustaining their own socioeconomic well-being, but also, imperative for sustaining the livelihoods of their communities (Sayma, *et al* 2010).

The farmers' average age was 39 years, which is very good for decision taking on early adoption of improved technologies in active home garden production. This is true because, young farmers are expected to be more innovative and risk taking (IFAD, 2020). Meanwhile, greatest percent (78.1%) of the sampled farmers are married with average family size of 10 members; this implies that the farmers are mature enough with good family size that can propel them to adopt any improved agricultural technologies which could increase their level of farm output in order to meet up with households needs. More so, large household size is commonly expected to increase adoption, as it is used as a proxy for labour availability in places with labour market imperfections. Although, the exact effect depends on whether the technology is labour saving or increases labour needs (Munguia and Llewellyn, 2020). However, their level of education was poor with majority (45.3%) and (35.9%) were only able to have secondary and primary education respectively, while only (18.8%) got tertiary education. This low level of education would affect their level of knowledge, acceptance and adoption of improved agricultural technologies, which in turn will affect their level of farm output. This is because; good level of education is expected to affect technology adoption positively since new technologies require an understanding of the expected returns from a new technology (Huffman 2020). High level of education among the farmers would likely make them more responsive to many agricultural extension programmes and policies (Agwu *et al*.,2008). Meanwhile, the farmers have spent an average of 14 years in home garden production which would enhance their level of knowledge on traditional home garden activities. Agwu *et al*., (2008) reported that long farming experience is an advantage for increased home garden productivity and could encourage rapid adoption of farm innovations. Data in table 1 also, shows that each farmer's farm size is less than a hectare. Home garden cultivation is usually done on small land area around the homestead (FAO, 2014). This has resulted to poor average annual income of about N38,000.00, from home garden activities, which might hinder them from meeting up with costs associated with adoption of improve technologies. This is because, IFAD, (2020) has reported that high annual home garden income is expected to positively affect the adoption of new practices that require up-front cash investments such as use of improved seeds or fertilizers.

Data analysis in table 2 reveals that all (100.0%) of the farmers knew about improved seeds, while only 59.4% had used them. This is poor level of adoption. Mundlak, *et al*, (2004) has noted that most of improved seeds are high input responsive with higher economic returns compared to local varieties. All (100%) of the farmers interviewed in this study knew about manual irrigation system, which is necessary because of irregular and uneven pattern of rainfall throughout the year, especially during critical growth period of the crops. And so, 90.7% of them had been using it.

ISSN: 2814-0508

This is good level of adoption considering the facts that; irrigation has become necessary in order to avoid crops failure and meet up with pressure on growing food demand and provide low cost food to an increasingly world populations (Giordano, *et al*, 2017). Meanwhile none of the farmers studied or interviewed used mechanized system of irrigation on their home garden activities even when 60.9% of them were aware of that. Verma (2006) has stated that mechanized irrigation system enhances the productivity of home gardens due to timeliness of operations and precision in the application of water. One hundred percent (100.0%) of farmers were aware of pesticide use in home garden, since, pests were notable problems that need to be removed, however, it was adopted by 28.8% only. This very poor level of adoption could be as a result of having very poor knowledge about pesticide, poor income or simply avoided to avert risk. Nevertheless, Kroening and Frishel, (2016) has reported that pesticide can increase production in the gardens and fields by reducing loses caused by insects, diseases and weedy species. Similarly, 100.0% of farmers had knowledge of herbicide, and, it was applied by 21.8% of them, which is very poor level. This could be attributed to the fact that Gianessi (2013) had opined that herbicide reduces manual weeding, that is time-consuming, physically demanding, and often detrimental to the farmers 'health and well-being. Furthermore, all (100%) of the farmers were cognizant of fertilizer use, which improves soil fertility, that sustains plant growth and optimize crop yield, thus, 71.9% of the farmers had used fertilizer in their home gardens. This good level of fertilizer use may have been necessitated by increased yields and higher profit return from produce sales. IAEA/FAO, (2020) noted that advancing food security and environmental sustainability in home garden systems requires an integrated soil fertility management approach such as use of fertilizer, organic inputs, among others, that maximizes crop production and minimizes the mining of soil nutrient reserves. Seventy-five (75%) of farmers were aware of farm and crops arrangement and it was practiced by 43.8% of them. This is very poor level of adoption considering the facts that farm and crops arrangement exposes the orderliness and beauty of home garden and crops, and facilitates post planting activities such as weeding, spraying of pesticide and liquid plant food, farm observation, harvesting of crops, among others. Again, all (100%) of the farmers were aware of electricity but none of them used it, due to total power failure in the area. This lack of electricity could be a significant constraint to adoption of improved technologies, growth and productivity of home garden; in that it induces growth in the rural economy including agriculture by bringing about higher agricultural income and improved opportunities for nonfarm labour (Gilberto, 2012). Over ninety percent (90.7%) of farmers were aware of crop rotation, and 84.4% of them rotated crops in their home gardens. Crop rotation helps to maintain soil structure and nutrient levels and to prevent soil borne pests from getting a foothold in the garden (Rudolph *et al*, 2020). Finally, none of the farmers know about vertical farming such as hydroponics, aquaponics, aeroponics and use of drone in home garden production, because these new technologies were yet to be introduced in the area. These new technologies could have been a helpful answer to frustrations with traditional home garden practices. This is because, it provides longer growing capacity, less water consumption, and improved crop predictability due to controlled environment which aims at optimizing crop growth and yield (Birky and Jeff,2016). Benke and Tomkins, (2017) has noted that the main advantage of utilizing vertical farming technologies is the increased crop yield that comes with a smaller unit area of land requirement.

It was found from the result in table 3 that inadequate finance (x=3.45) and inadequate or lack of access to loan (x=3.42), were notable adoption constraining factors; that can impede increased investments in home garden, particularly in the identification and promotion of improved agricultural technologies and practices (AASR, 2016). This is because, resource endowments (including various wealth indicators and access to off-farm income) are significantly correlated with higher adoption of home garden related practices (IFAD,2020). Lack of modern power production equipment (x=3.35), such as cultivators, irrigation sprinklers, hedge trimmers, mini tractors, etc was found to be militating against adoption practices in the area. FAO, (2021) stated that sustainable home garden production with the use of modern power equipment that reduces drudgery can contribute significantly to the development of value chains and food systems as it has the potentials to render postharvest, processing and marketing activities more efficient, effective and environmentally friendly. Lack of processing and storage facilities (x=3.34), was identified as an impediment to use of improved agricultural practices in home garden, in that it effects farmers income, as they were often compelled to sell their produce at very low prices to avoid much losses due to post harvest spoilage. TNUA, (2015), opined that processing and storage provides employment and higher income through price advantages. Pests and diseases attack (x=3.31), was observed as a problem. Due to the fact that they affect food crops, causing significant losses to farmers and threatening food security (FAO, 2021). Small available land (x=3.26), that could not accommodate the use of power equipment on home garden production was also a problem. Mehari and Abera, (2019), stated that as the area of the gardens is limited, the improved agricultural activities undertaken inside the gardens will also be minimal, thus, the output. Poor produce prices (x=3.20), due to glut, uncontrolled market price system and poor purchasing power of the consumers in the area was seen as a challenge. This is because, high produce price is known to stimulate more food production including fruit and vegetables that can generate new jobs and improve welfare (FAO,2011). High cost of inputs (x=3.17), as a result of poor income and high level of inflation rate in the country would hamper adoption of improved agricultural practices in home gardens. Because if the cost of input rises then the cost of production will also increase and it will tend to reduce urge to produce and create some cut in production and so, less need of the improved product. Changes in rainfall pattern and other weather conditions (x=2.88), affects adoption of improved practices in home garden. As it increases crop diseases incidents, uncertainties, risks and causes drastic reductions in soil fertility (Kashaigili *et al.,* 2014). Inadequate extension services (x=2.85), was noted as a constraint to adoption of improved agricultural technologies. This agrees with, Dideon-Abbeam, *et al.,* (2018), that adequate extension services would have been the major channel for disseminating information on improved agricultural technologies to home gardeners, and it is expected to increase garden productivity and revenue, reduce poverty and minimize food insecurity.

CONCLUSION AND RECOMMENDATION

From the findings of this study it was concluded that farmers were aware of all the examined improved agricultural practices on home garden activities, with the exception of vertical farming and use of drones. However, use of manual irrigation, crop rotation and fertilizer, was outstanding in the area, which is followed by use of improved seeds. While, farm and crop arrangement, pesticide and herbicide use, were very poorly adopted. Use of mechanized irrigation system, electricity or solar power, vertical farming and use of drone were not adopted at all. Nonetheless, some notable factors such as inadequate finance, inadequate or lack of access to loan, lack of modern power equipment and lack of processing and storage facilities significantly constrained adoption of improved agricultural practices in the area. It was therefore recommended that both state and local government as well as non-governmental organization should offer farmers soft loan to enable them meet up with cost of adequate adoption of improved agricultural practices. More, so, NIHORT Mbato, local and state government should send adequate trained extension agents to the area, to intimate the gardeners on the unavoidable needs of improved agricultural practices.

ABSTRACT

Cashew tree is of economic importance grown commercially in some areas in Nigeria such as Oyo state for its apple and especially the nuts. Over the years, cashew farming has experienced a decline due to reduction in cashew farmers and senile cashew trees. The goal of this paper is to identify and proffer solutions the constraints in cashew farming peculiar to unemployed graduates in Oyo state. Some selected areas where considered in Oyo state where data on socio economic character, awareness of cashew tree and its importance and constraints of graduates' involvement in cashew farming were collected using questionnaires. 90 respondents were considered in the survey. Data was analyzed using SPSS statistical package. Result showed that 46% of the unemployed graduates were between the ages of 28-31 years. The study also showed that 85.6% knows the economic importance of cashew while 91.1% knows cashew farming as profitable. Lack of fund ranked first of the constraints to cashew farming. Majority of the graduates are aware of the importance of cashew. Zero or single digit interest loans or grants should be given to the unemployed graduates so as to encourage them in participating in cashew farming thereby increasing its production.

Key words: Cashew, unemployed, constraints, farming, graduates, production

INTRODUCTION

Cashew tree (*Anacardium occidentale* L.) is a popular specie of the Anacardiceae family (Subbarao *et al*., 2011). Commercial farming of cashew started in 1953 (Akinwale and Esan, 1989) but now cultivated in about 20 states in Nigeria with Kogi, and Oyo state among the heavy producers. It is among the important edible nuts with high demand in the world market with Nigeria among its leading producers. The tree brings substantial income to both the farmers and the local buyers (Elijah, 2015). Cashew is mostly ventured into for its wood, apple and more importantly the nut (Adeigbe, *et. al*., 2015).

There is a noticeable decline in the yield of cashew in most growing areas in Nigeria due to decrease in the number of cashew farmers over time (Hammed *et. al*., 2008) and increase in moribund cashew trees. Globally, Nigeria contributes about 2.52 percent share of the total export of cashew nut in world market which is low compared to the contributions of other cashew producing countries (FAOSTAT, 2019). Nigerian cashew nut value chain has not been fully exploited, despite its money making potentials. (Adesanya *et. al*., 2021).

Oyo state is a major cashew producing state in Nigeria with high population of its graduates seeking for employment or a sustainable source of income. Therefore, the objective of this study is to:

1. Understand the constraints of unemployed graduates in Oyo state to cashew farming.
2. Identify ways of increasing youths or graduates' engagement in cashew farming.

MATERIALS AND METHODS

The study was conducted in Oyo State with the coordinate 8.1574° N, 3.6147° E which is located in South Western Nigeria. It is the 5th ranked most populated state in Nigeria with a population of about 7,840,864. The vegetation pattern of Oyo State is that of rain forest in the south and guinea savannah in the north. Some selected areas were considered due to their dense population and high numbers of graduate youth. Purposive sampling was also used in selecting 90 respondents as they are either job-seeking graduates or unemployed but running a not too sustainable business before participating in the survey. Data were collected using questionnaires. The data collected were socio-demographic characteristics of the respondent, awareness on cashew tree and its importance and constraints to graduates participation in cashew farming. Data obtained were analyzed using SPSS statistical package (version 22) and subjected to descriptive statistics such as frequency table and percentage.

RESULTS AND DISCUSSION

The table 1 on socio-economic characteristics of the unemployed graduates showed that 59.3% are male while 40.7% are female. 46% were between the ages of 28-31 years, 23.3% were between the ages of 32-35 years while 22.2% were between the ages of 24-27 years which implies that majority are still in their very active youthful age which gives them an advantage of success if engaged in cashew farming. 58.2% are single while 41.8% are married. 55.6% had B.Sc. qualification and 34.5% had M.Sc. qualification which shows that majority of the graduates has highly invested in their education.

Table 1: Socio-economic characteristics of the respondents

Socio-economic characteristics	Frequency	Percentage
Sex		
Male	54	59.3
Female	37	40.7
Age		
20 – 23	2	2.2
24 – 27	20	22.2
28 – 31	42	46.7
32 – 35	21	23.3
36 – 39	5	5.6
Marital Status		
Single	52	58.2
Married	38	41.8
Academic qualification		
National Certificate of Education (NCE)	3	3.3
Bachelor of Science (B.Sc.)	50	55.6
Master of Science (M.Sc.)	31	34.5
Other	6	6.6

Source: Field survey: 2021

The table 2 on distribution of respondents by their awareness of Cashew tree and its importance showed that 98.8% can identify or are aware of what a cashew tree is which indicate that cashew tree is a well-known tree. 100% of the respondent knows what a cashew nut is which showed that cashew nut is a popular nut among the graduates. 85.6% knows what a cashew apple is. 93.3% knows cashew as a crop of economic importance, also 85.6% is aware of cashew to be a major export commodity in Nigeria which indicates that importance of cashew both as an economic crop and a major export commodity is well known. 91.1% knows cashew farming to be profitable. 64.4% knows Nigeria as one of the leading producers of cashew nut while 35.6% are not aware.

Table 3 shows the constraints to graduates participation in cashew production and value chain. Lack of fund ranked 1st of all the constraints to cashew production considered as it is one of the discouraging factors when considering plantation farming. Insecurity ranked 2nd of the constraints which is a major problem being currently faced by Nigerian farmers. Pilfering which is one of the major problem encountered by cashew farmers ranked 3rd. Little or no knowledge in cashew farming ranked 7th and 3 to 4 years wait before fruiting was ranked least (11th) of all the constraint.

Table 2: Distribution of respondents by their awareness of Cashew tree and its importance

Awareness of Cashew tree and its importance	Aware	Not aware
Can you identify a cashew tree?	88 (97.8)	2 (2.2)
Do you know what a cashew nut is?	90 (100)	0 (0.0)
Do you know what a cashew apple is?	77 (85.6)	13 (14.4)
Do you know that cashew tree is of economic importance?	84 (93.3)	6 (6.7)
Do you know that cashew nut is a major export commodity in Nigeria?	77 (85.6)	13 (14.4)
Do you believe that cashew farming is profitable?	82 (91.1)	8 (8.9)
Do you know that Nigeria is one of the leading producers of cashew nut?	58 (64.4)	32 (35.6)

CONCLUSION

Larger population of the job hunting graduates are still in their very youthful age, well-educated and unemployed for about an average of 4.98 years. Creating job opportunities for this population by engaging them in cashew production will help increase the decline experienced in cashew production and output thereby serving as job opportunity and a major source of sustainable income for the unemployed youths. Cashew tree, its nuts and apples are well known as a profitable economic and export crop in Nigeria, therefore necessary trainings and empowerment must be adopted to help monetize this knowledge thereby increasing cashew production. Government should work in partnership with commercial banks and bank of agriculture in giving zero or small interest loans to graduates or youths who wants to engage in farming activities such as cashew farming since it is a capital intensive project. Regular dissemination of information on cashew farming and processing, farm security and anti-theft lectures should be passed via mass media, social media and seminars by research institutes such as Cocoa Research Institute of Nigeria whose one of its mandate crops is cashew.

ABSTRACT

Cashew production has contributed greatly to Nigeria economic growth, unfortunately its production is faced with so many constraints that if not urgently addressed it can make cashew production to go into extinction. This study therefore examined emerging constraints facing cashew production in two local governments area of Kogi State, North central Nigeria. Data were obtained through structured questionnaire administered to 60 randomly selected cashew farmers from the study area. Data were analysed using descriptive and inferential statistics. The result revealed that majority of the respondents were male (70%), married (73.3%) with mean age of 48years. Majority (81.7%) had formal education, 50% had between 1-5 persons in their household, and 45% had farm size of between 6-10ha. Major production constraints are lack of access to credit facilities (mean =2.70 ranked 1st), price fluctuation (mean 2.68 ranked 2nd), farmers-herders' clashes (mean 2.60 ranked 3rd) and sharp practices of middle men (mean 2.59 ranked 4th). Respondents accessed inputs such as cashew nuts (95%), cashew seedlings (78%) from research institute (CRIN), farm implements (100%), chemical (90%), fertilizer (60%) from friends and family, input dealers and farmers' cooperatives society respectively. Majority of the respondents (58.3%) had negative attitude towards cashew production constraints. Chi-square analysis revealed a significant relationship between level of education (X^2= -11.622, P=0.011), primary occupation (X^2=7.360, P=0.061) and constraints faced in cashew production. It is therefore necessary for both government and non- government organizations to help in policies formulation that will reduce cashew production constraints

Key words: Assessment, Cashew Farmers, Production Constraints

INTRODUCTION

The Cashew plant, *Anacardium occidentale*, belongs to the family of Anacardiaceae is a native of central and South America with its main centre of variation in eastern Brazil. Its importance as an agricultural commodity lies in the values derivable from its fruit (nut) and apple. products from the whole fruit include the edible kernel, cashew nut shell liquid (C N S L) and the apple which can be consumed fresh as well as prepared into syrup, jams, jellies, beverages or candied fruits (Opeke, 2005) Cashew nut production trends have varied over the decades. Currently, 75 to 80% of cashew nuts produced in Nigeria are exported, as only very few companies are involved in local processing of the produce (Aliyu and Hammed, 2008).

The annual world production of cashew nuts was about 3,186,039 tons and Nigeria was rated the second among the top ten producers with 660,000 tons making the sector a major contributor to Nigeria's non-oil GDP. Vietnam is the highest producer with 961,000 tons (FAOSTAT, 2010). The estimated export value varies from US$ 25- 35 million annually, and supplements the income of about 50,000 farmers and an additional 55,000 people who are employed down its value chain (Nugawela and Oroch, 2005; Adeigbe *et al*., 2015). Out of 2.6 million tonnes of raw cashew nuts produced in the world, 42% of it come from Africa out of which 90% is exported while only 10% is left for domestic consumption.

Nigerian nuts have consistently served the Indian and Vietnamese cashew factories and in recent years have added the Brazilian market. The kernels are well accepted in the United State of America and Western Europe because of the high quality of the produce (Aliyu and Hammed, 2008). The constraints militating against cashew production are production constraints biotic, environmental, breeding, climatic and land; marketing constraints and processing constraints. Production constraints results from damages from different insect species at different stages of production. These result into high loss of yield. It attacks the leaf causing black leasion on petioles or the leaf surface. it also attacks the stem which appears as a discolored and lesion which also occurs on fruits and developing nuts. In situation of high infestation of these insect on a farm. It eats up the whole shoot and it dies or the entire tree looks burnt. This brings about great loss of income to farmers (Aliyu, 2010).

According to Agbongiarhuoyi *et al.* (2015), cashew grows almost everywhere in Nigeria with production spanning across 27 out of 36 States in all the geo-political zones. Irrespective of the predominance of this crop in many states, yield per hectare is not encouraging. There is abandonment and significant decline in yield of cashew production in most growing areas of Nigeria as a result of discovery of crude oil by federal government in early 1970s (Hammed *et al.,* 2008).

According to Agada and Sule (2020) The problems of cashew production include; old trees, deforestation, low yield varieties, dominance of small holdings and wild varieties, land acquisition, high cost of inputs, climatic conditions, diseases and pests, fire outbreaks, post-harvest losses, infrastructural constraints, poor qualities, market price of the product and the competition amongst the local buying agents. Apart from this, several authors had worked on the problems facing cashew production in Nigeria. for instance, Aliyu and Hammed (2008) worked on constraints to cashew production in Nigeria. Agbongiarhuoyi *et al.* (2015) considered factors associated with low yield of cashew among farmers in growing areas of Nigeria. Also, Oluyole *et al*. (2015) investigated constraints in cashew production among cashew farmers in Southwestern Nigeria. While Uwagboe *et al.* (2010) considered constraints of farmers in cashew production, a case study of Orire L.G.A of Oyo state Nigeria.

In order to solve some of these cashew production constraints, Cocoa Research Institute of Nigeria (CRIN) with research mandate in cocoa, kola, cashew, coffee and tea has recommended some cashew production technologies that if farmers adhere strictly to it will reduce some of these production constraints. These are regular pruning, maintenance of recommended spacing (6m x 6m or 9m x9m), cashew rehabilitation techniques, replacement of death/ missing stands, prompt harvesting of ripe cashew apples, regular weeding and planting of improved varieties of cashew nuts and seedlings

The main objective of the study was to assess the constraints limiting cashew production among farmers in Kogi- State. The specific objectives were to describe socioeconomic characteristics of the respondents, ascertained some agronomic practices, identify constraints to cashew production, identify sources of input and determine attitudes of farmers towards cashew production constraints. The hypothesis of the study was stated in the null form; there is no significant relationship between socioeconomic characteristics of the respondents and the constraints to cashew production.

MATERIALS AND METHODS

A multi-stage sampling procedure was used to select respondents for the study. Stage1: Kogi State was randomly selected from North Central. Stage 2: two Local Government Areas (LGAs) noted for cashew production were chosen. These are Dekina and Ankpa. Two villages per LGA where cashew is well produced were selected. Stage 3: Fifteen farmers were selected in each village to make a total number of sixty respondents. A list of cashew farmers was obtained from the Tree Crop Units (TCU) in the State ministry of Agriculture. A structured interview schedule was used for field data collection from cashew farmers in the study areas. Descriptive statistics and chi-square were used in data analysis. The variables were measured at 0.05 Level of probability.

RESULTS AND DISSCUSSION

The socioeconomic characteristics of the respondents

The socioeconomic characteristics of the respondents are shown in Table 1. The result revealed that greater percent (70%) of the respondents are male while 30% were female. This result is in agreement with Uwagboe *et al.* (2010) who found out that 84.5% of cashew farmers in orire local government area of Oyo State are male. The result also shows the mean age of farmers as 48 years with 73.3% married. It indicates that farmers are still very energetic and they are still in their productive age. Also, the greater numbers of married farmers in the study areas is as a result of the tedious nature of cashew farming that cannot be done alone. The mean household size was 9.7 persons. The implication of this is that farmers with higher numbers of household size tends to enjoy cheap labour for farm enterprise. This is in agreement with Onuk *et al.* (2013) who explained that household labour help in solving labour related issues on farm. Eighty-two percent of the respondents had primary school leaving and above, it shows that greater percentage of the respondents can read and write, this may be as a result of influxes young school leaver into the profession. According to the table, 66.6% of the respondents cultivated above 5 hectares while the mean farm size is 11.1hectares. This result contradicts the result of Agbongiarhuoyi *et al.* (2015) where only 47% of farmers had above 5 hectares

Utilization of some agronomic practices

The distribution of respondents based on utilization of some cashew agronomic practices is indicated in Table 2. The result show that 60%, 45% and 41.7% of the respondents regularly practicing timely harvesting of cashew nuts, regular pruning and recommended planting spacing with mean scores of 1.53, 1.35 and 1.27 respectively. The result of regular pruning and timely harvesting is in tandem with the work carried out by Agada and Sule (2020) where 89.5% of cashew farmers pruned regularly and 100% of cashew farmers harvest regularly. Also, 78.3% and 58.3% occasionally practiced gapping up/suppling of death stands and use of improved cashew seedlings/nuts while 73.3% never practiced cashew rehabilitation technique. Cashew rehabilitation technique is the process of making unproductive cashew plantation to be productive by increasing its economic life span. It is a new technology so efforts should be geared towards training of famers on how to carry it out.

Table 2: Percentage distribution of the respondents based on agronomic practices

Agronomic practices	Regularly		Occasionally		Never			
	Freq	%	Freq	%	Freq	%	Mean	Rank
Regular pruning	27	45.0	27	45.0	6	10.0	1.35	2nd

Constraints encountered in cashew production

Table 3 presents the various production constraints faced by cashew farmers and their corresponding degree of severity. Constraints such as no access to credit facility (76.7%), price fluctuation (70%), farmers-herders' clashes (66.7%) and sharp practices of middlemen (65.0%) were found to be major constraints faced by the respondents. Credit is very important in cashew production as farmers need money to purchased so many things like improved seedlings/nuts, agrochemicals, some farm equipment, paid wages to laborers. Akinbode (2013) explained that it is difficult for farmers to get loan from banks as a result of stringent and high interest rate demanded by commercial bank. In addition, transportation problem (73.3%), unavailability of labour (66.6%), irregular rainfall (55.0%) and prolonged draught (53.3%) were considered as minor constraints affecting cashew production in the study areas. This result is similar to the report of Oluyole *et al.* (2015) who found out that farm activities, age of farm , inadequacy of labour, access to market information and inadequate credit are part of many challenges of cashew production in Nigeria In clear term, no access to credit facilities, price fluctuation, and farmers-herders' clashes ranked 1st, 2nd, and 3rd respectively as the most serious production constraints facing cashew production while transportation problem(13th), and irregular rainfall (14th) ranked least among production constraints in this study.

Sources of inputs

Table 4 shows that majority (95% and 78%) of the farmers got their cashew nuts and cashew seedlings respectively from research institutes (CRIN) while only 10% farmers got their cashew nuts from input dealers and 40% got cashew seedlings' from family and friends. Eighty percent (80%) of the farmers got fertilizer from input dealers while 60% of farmers got it from farmers' cooperatives society. Majority (90%) of farmers got chemicals from input dealers while only 10% got same chemicals from cashew farmers association of Nigeria (CFAN). All the farmers got farm implements from friends and family. The major sources of loan to farmers is friends and relatives (88%), and farmers' cooperatives (64%) while only 9% farmers procure loan from agric bank. High interest rate and collateral security demanded by agric banks discouraged farmers from taken loan from the bank

Table 3: Percentage distribution of respondents based on constraints encountered in cashew production

Constraints	Major Freq	Constraint %	Minor Freq	Constraint %	Not a Freq	Constraint %	Mean	Rank
No access to credit	46	76.7	10	16.7	4	6.7	2.70	1st

Farmers attitudinal disposition to cashew production constraints

The results of farmers' attitudinal disposition to cashew production constraints is shown in table 5a. According to the table, all the farmers (100%) agreed that credit facilities are readily available to farmers; 78%, 63.3% and 80% also agreed that unstable government policies affect cashew production, farm labour is not cheap and affordable and farmer-herders' clashes are big challenges to cashew production respectively. However, 75%, 71.6%, and 86.6% disagreed with the statement that information on GAP are readily available, pest and diseases do not affect cashew production and it is cheap to transport cashew nuts

Farmers level of attitudinal disposition to cashew production constraints

Farmers attitudinal disposition was categorized into positive and negative (Table 5b). This was determined as the mean attitude scores was computed and used as the benchmark, such that respondents whose scores are below the mean attitude scores were categorized as negative attitudinal disposition, while scores equal to or greater than the mean score were categorized as having positive attitudinal disposition. The result shows that majority (58.3%) of the respondents had positive disposition to cashew production constraints while 41.7% had negative disposition

Hypothesis testing

Chi-square result of the relationship between respondents selected socioeconomic characteristics and constraints to cashew production as revealed in table 6. It shows a significant relationship occurred between educational level (X^2 =-11.622; P< 0.011), primary occupation (X^2= 7.360; P< 0.061) and constraints to cashew production. It implies that education inversely influences constraints faced by respondents. The implication of this is that the more educated farmers experienced lesser constraints as compared to those who are not educated. in other to solve emerging constraints faced by cashew farmers, education is very important. Also, the positive significant relationship between primary occupation and constraints indicates that respondents whose primary occupation is farming are more constraint in their farming activities compared with those who took farming as their secondary occupation. However, Marital status and Religion did not have any significant relationship with constrains to cashew production.

Table 6: Chi-square analyses between respondents' socioeconomic characteristics, attitude and constraints in cashew production

Variable	X^2	Df	r-value	p-value	Decision
Marital status	3.573	3	-	0.311	NS
Religion	1.195	2	-	0.550	NS
Education	-11.622	3	-	0.011	S
Primary occupation	7.360	3	-	0.061	S

CONCLUSION AND RECOMMENDATION

The study concludes that cashew farmers are still in their productive age. Farmers frequently utilized most cashew agronomic practices. This study had revealed array of constraints facing cashew farmers which might affect cashew production in commercial purposes these include; lack of access to credit, price fluctuation, farmers-herders' clashes, sharp practices of middlemen, price fluctuation etc Based on the importance of cashew production and its products to Nigerian populace, it is therefore necessary to encourage cashew farmers so that production can be increased. Farmers need to be encourage by making available for them credit facilities as most of them depend on personal savings and money gotten from family and friends to finance their farming operation. Inputs should be subsidized by government and made available to farmers in large quantity so that farmers can be motivated to continue and increase production.

ABSTRACT

The study examined constraints to plantain production among farmers in Ido Local government area of Oyo State. A total of 120 plantain farmers were sampled and data was gathered with the use of a structured questionnaire. The results revealed that 63.1% of the respondents were male and about 59% had tertiary education. Major benefits that respondents derived from plantain were, as a source of food (76.2%) and income (75.4%). Moreover, constraints faced by the respondents were cost of planting materials (68.9%), bad road network (63.1%), high transportation cost (60.7%), among others. The study thus recommends that training opportunities should be made available for the plantain farmers in the identified areas, especially on ways of generating planting materials.

Key words: Carbohydrate, export, high labour cost, starch

INTRODUCTION

Plantain (*Musa paradisiaca*) is one of the staple foods in developing countries mostly in Western and Central Africa. Globally, it considered important after rice, wheat, and maize with respect to gross value of production (FAO 2018). It is estimated that about 70 million people in West and Central Africa obtain more than 25% of their carbohydrates from plantains, making it a major energy food in these areas. Seven of the top 10 plantain producing countries globally are in Africa. Ghana, Cameroun Nigeria and Guinea and Côte d'Ivoire are in West Africa. Despite the huge potentials offered by plantain, Nigeria is not prominent among plantain-exporting countries as the production is mostly for local consumption (Akinyemi et al., 2008). Cameroun exports approximately 4.31 million tons of plantains yearly followed by Ghana with an average annual export volume of 3.95 million tons (FAO 2018). The sustained production of plantain in Nigeria is limited by several factors like pests and diseases, low technology adoption and environmental factors, especially among smallholder farmers. However, there is a need to continuously boost plantain production through innovative concepts together with continuous training and capacity building for farmers to assist them understand new concepts and apply new knowledge in farming (Ibitoye and Onimisi 2013). Thus, to improve agricultural productivity, farmers' competencies need to be up scaled through appropriate intervention and trainings that could lead to improvement in their skill, knowledge and attitude. For this to be successful, farmers' training needs or shortfall in knowledge, skills and abilities must be assessed. This study was therefore designed to access the constraints to plantain farmers in Ido Local Government Area of Oyo State.

MATERIALS AND METHODS

The study was conducted in Ido local Government Area of Oyo State, which is in the South-west Geopolitical Zone of Nigeria. The local Government has a land area of 986km2 and a total population of 103,261. The population of the study was the plantain farmers in Ido Local Government Area, Oyo state. Multi –stage sampling technique was used in selecting the respondents. The first stage was a selection of Odo-Ona Apete within Ido Local Government Area. The second stage involved the random selection of 120 plantain farmers. A structured questionnaire was used to elicit information from the plantain farmers on their personal characteristics, benefits of plantain, training needs and constraints to plantain production in Ido Local Government Area of Oyo state. The variables considered are:

Age: The age of respondent was measured in actual years.

Sex of respondents: This was categorized into male and female measured by assigning scores of 1 to male and 2 to the female respondent.

Marital status: The marital status of the farmers was categorized as single, married, divorced, widowed, separated with 1, 2, 3. 4, and 5 assigned respectively.

Sources of information on plantain production: It was measured based on 2-point scale: yes =1, No = 2.

ISSN: 2814-0508

Benefits derived from plantain production: It was measured based on 3-point scale: major =1, moderate = 2, minor = 3.

Constraint to plantain farmers: This was measured was based on 4-point scale: very severe =1, severe =2, moderate = 3, not severe = 4.

RESULTS AND DISCUSSION

Socio-economic Characteristics of the Respondents

Table 1 shows the frequency distribution of respondents according to their socio-economic characteristics. This table reveals that there were more male plantain farmers in the study area and that most of them (76.1%) are married. This agrees with the findings of (Edeoghon et al. 2008), that agriculture is mostly practiced by married people to make ends meet and cater for their children. Furthermore, the result shows that 38.0% of the respondents were in middle age ranging from 40-49 years and about 59% of them have tertiary education. Educated farmers have more access to information on farm improvement techniques and credit than non-educated farmers, education affords farmers the ability to think and make necessary decision associated with their farming enterprises, (Barmon et al. 2012). The results also revealed that 37.7 percent of farmers has spent 6-10 years in farming, which is relatively long time in farming and therefore should equip them with better knowledge pf farming (Alexander et al. 2018). Moreover, farm size of most of the respondents (54.2%) was between 1 and 5 acres while 43.4% of the respondents was involved in mixed cropping. Large farm size increases agricultural productivity, improves farmers' technicality, resource use efficiency as well as easy adaptation to climate change (Onubuogu et al. 2014). Almost half (45.9%) of the respondents were members of farmers' association. At harvest, 59% of the farmers harvest plantain when it is mature and unripe; (28.7%) of the respondents sell their products to the wholesalers, while (36.1%) feed the stem of plantain to animals after harvest. Also, 46.7% of the farmers consume the produce does not meet grading standard.

Constraints Faced by Plantain Farmers

The constraints experienced by plantain farmers (table 2) show that most plantain farmers face very severe constraints, some of which are cost of planting materials (68.9%), bad road network (63.1%), high transportation cost (60.7%), high labour cost (50.8%). Previous studies such as Idumah et al (2016) and Akinyemi et al. (2013) had also identified high cost of labour as a major constraint faced by plantain producers in Nigeria Also, few of the respondents experienced severe constraints such as timely availability of suckers (36.9%), inadequate market information (34.4%) and non-availability of improved planting materials (32.0%). Moreover, climate change and limited productive land were moderately severe constraints faced by few of the respondents (29.5% and 28.7% respectively) in the course of plantain production. The study identified high cost of planting material as major constraints to plantain production in the area and recommends training opportunities on ways of generating planting materials.

ABSTRACT

This study investigated rural youths' participation in Community Development (CD) activities in Oluyole Local Government Area of Oyo State. One hundred and ten youths were selected for the study through a multistage sampling procedure. Structured interview schedule was used for data collection. The data were analyzed using frequency counts, percentage, weighted mean and mean score ranking. Results show that most of the respondents were male (56.4%), married (64.5%) and aged between 26 – 30 years old (51.8%). Attendance and punctuality at community development meetings ranked highest amongst CD activities with weighted mean score (WMS) of 3.50 and 3.65, respectively. Participation at planning stage of CDAs recorded WMS of 2.94, implementation stage (3.14) and evaluation stage (2.75). Constraint militating against youths' participation in community development activities included poor monitoring which recorded the WMS of 5.60, poor team spirit (4.80), and funds' mismanagement (3.57), gender bias (3.05). The study concluded that participation in CDAs by youths in the study was at average level.

Key words: CDA, Rural youth, WMS, Constraint

INTRODUCTION

Rural youths' have a great role to play in community development in Nigeria as they are being considered to be the active working group. The youth at present, constitute about 60% of Nigeria's population and have over the years made significant contributions to National Development (Vision 2010 report, 2005). The concept of youth has been defined by Nwachukwu (2008), as the period in an individual life which comes between the end of childhood and entry of adulthood. The United Nation defined youths as individuals between the lower age of 17 years and upper age limits of 39 years. Youth, the state of being young, is a transitional period in personality development that bridges the years between childhood and adulthood (D`Souza, 1970). The age bracket varies among authorities ten to twenty years (Shingi et al., 1980) and 10-30 years (Anonymous, 2000). In some societies, as long as one remains a bachelor or spinster one is a youth! Youths possess unique capabilities; dynamism, strength, adventure, ambition, hilarity etc. (Udah, 2001; Waldie, 2004; Akwiwu et al., 2005). One eminent problem Nigeria is facing today is how to tackle income disparity between urban and rural centers especially in youth situations.

Youths have a solution to the problem, if they will mobilize their fellow youths to embark on community development and self-help projects that will make them compete among themselves and other youths around the world. Already some communities in Nigeria have formed their Youth's Community Development Associations (YCDA) long ago for the improvement of their living conditions. The various governments in Nigeria have in the past introduced various community development programmes for the benefit of all citizens irrespective of sex. Programmes includes: Directorate of Food, Road and Rural Infrastructure (DFRRI), National Agricultural and Land Development Authority (NALDA), National Directorate of Labour (NDL), Small and Medium Enterprises (SME) etc. However, these programmes seem to have achieved little. Unfortunately, the present situation makes it even more difficult to explore youths' full potential in community development. In order to stimulate the interest of our youths' in community development; government has to put in place certain measures that will make youths' to be self-developed, independent, motivated, spirit of leadership and self-employed in order to contribute to development of their community and this will in turn help to have the courage of sense of belonging, leadership skills anywhere they found themselves.

Community development is the process whereby some citizens mobilize their members so as to map out a strategy of improving their community through collective efforts. Collective efforts mean the ability to have full participation of members to be able to make use of their local resources in order to improve their living condition and standard. But the United Nations (1963)

ISSN: 2814-0508

defined community development "as the process by which efforts of the people themselves are united with those of the government authorities to improve the economic, social and cultural conditions of the communities to integrate them into the life of the nation and to enable them to contribute fully to national progress". Therefore, the United Nations definition of community development implies the participation of both the community and the government. Hillman (1960) has however defined community development as the method of helping local communities to become aware of their resources in such a way to satisfy some of their needs and in so doing, acquire the attitudes, experiences, and cooperative skills for repeating this process using their own initiatives.

Community Development, according to Ajayi (1995) and Hanachor (2012), is a social process by which human beings can become more competent to live with and gain some control over local conditions and the changing world. Sustainable community development cannot take place through force or order, but is most likely to happen when all actors participate and share their ideas, visions and responsibilities equally and democratically in steering and implementing their community or village development activities (Ajayi, et al, 2006). According to Emeka (2012), one approach in creating sustainable rural development is through giving the main actors (villagers living in the community) an equal opportunity to think and plan their own future. This underpins the need for effective leadership at the local community levels in order to harness the efforts of the rural people towards their own development.

Youths are great assets in the society. This is true because youths have played a great role and are still playing an important role in community and rural development. Many Nigerian youths lives in the rural areas and have being trying their best to improve their status through the community development programmes/Activities. The issue is that youths need to participate actively in community development as they will one day become self-sufficient. Youths have realized the importance of self-help projects in improving the way of life and living standards of their communities. Youth's participation cannot be over emphasized as youths are deeply involved in self-help projects in various local governments in Nigeria. However, Ekong (2003) argued that the youth have been active participant in the happening of their own destiny as well as building the development of the nation.

Participation or involvement of youths' in community development activities is a way of increasing their skills, knowledge, confidence, self-reliance and opportunity to collaborate and engage in sustainable development (Nelson and Wright, 1997, Akinbile et al, 2008; Kyle, 2009). Generally, the participation of youth in community development activities in Oluyole local government area in Oyo state, it is important in order to keep them together to love one another in the community. Since the communities throughout the state are faced with extensive growth pressure, significant socio-demographic changes and a growing youth population it at an alarming rate due mainly to the new nature of the State. Such condition suggests an important role for the youth to play in local planning and decision making (Unite Nation, 2002). The involvement of youth and their active collaboration with adult contribute to the local community development, while presenting opportunities for personal self-growth, skill enhancement and leadership development. It is also evident that successful youth or adult partnership encourages youth to develop the capacity to serve in organization and can actively become a community leader. Therefore, the United Nation (2002), posit that, youth participation is known to be prerequisite for overall development of community. This study is centered on the facts that youth are pivotal in the development of society which can be positive or negative. Some of the positive impacts of youth's participation in community development activities majorly in Oluyole Local Government Area are;

1. some of the schools in the LGA were dilapidated, as a result of compliment the effort of State Government in making sure school structure are made conducive for learning, the organization consulted a number of companies in the area to render help in this regard, out of all, Rom Oil Mills Nigeria Limited responded positively by renovating St. Martins Catholic School at Orile Odo Village to Modern School.
2. Clearing the bushes, cleaning of water channel and waste indiscriminately dumped by the major road sides in some part of LGA,
3. Training of youths in different skills such as computer training, hair dressing, make up and barbing, vulcanizing, embroidery, welding, catering services and fashion designing,

4. Organizing empowerment programme for the youths in computer training, hair dressing, make up and barbing, vulcanizing, embroidery, welding, catering services and fashion designing.
5. Reducing unemployment rate by securing employment for over 120 youths in the LGA.

These goals can only be achieved through the combined and collective efforts of all those who share the conviction that rural community development must be accorded a high priority in our drive for poverty alleviation and national self-sufficiency. To help bring a rural community to action, it is necessary for individuals and groups to provide good leadership. When good leadership is provided, the people participate voluntarily in the accomplishment of stated objectives. The approach to rural community development is always through local leaders who not only act as pioneers of projects but also help in influencing and motivating their people to action. For any rural community development to be successful, influential local leaders must be involved else they might undermine the progress of such programmes. Therefore, any agency or organization coming up with a development programme for the community must initially "clear" with these influential local leaders, a process otherwise referred to as legitimization. It is saddening to recall that rural community development was neglected by successive governments since colonial rule in Nigeria. For instance, according to Adebisi, (2009) while the colonial government concentrated their development projects such as roads, schools, hospitals, and pipe-borne water around the major cities and built network of roads to areas where they exploited our natural resources, the rural areas were completely left out.

Statement of the problem

The development and success of any community in rural or urban area majorly depends on the types or the categories of youths' in that particular community. Youth, the state of being young is a transitional period in personality development that bridges the years between childhood and adulthood. Many youths' in some community used their useful time, power, connection, knowledge and resources for something that are not useful for themselves or for the community. It is in this context that this study is aiming at evaluating the level of youths' participation in the community development activities of their area, examine the factors that are associated with their participation in CD activities, assessing their source of fund for execution of CD activities, and investigate the constraints of youths' participation in Community Development Activities in the study areas of Oyo State Nigeria.

Objectives of the Study

The broad objective of this study is to investigate the Rural Youths' Participation in Community Development Activities: A Case Study of Oluyole Local Government Areas of Ibadan, Oyo State.

Specific Objectives are to

- Identify the personal characteristic of youths' in the study area,
- Evaluate the level of youths' participation in community development activities,
- Examine the factors associated with youths' participation in CD activities in study area,
- Determine the constraints of youths' participation in CD activities.

The Research Hypothesis of the Study

The following null hypothesis will be used to test for the relationship between the dependent variable and independent variable of the study;

- There is no significant relationship between the age of respondents and level of participation,
- There is no significant relationship between the educational status of respondents and level of participation in community development activities,
- There is no significant relationship between the sources of fund for community development activities and the participation in the activities.

MATERIALS AND METHODS

Sampling Procedure

The study was conducted in Ibadan, Oyo State, precisely in Oluyole Local Government Areas of the State. The study area lies on the latitude 7^0 and 24^1 north and longitude 3^0 and 55^1 east of the glober axis with seasonal period of wet (Rain) and dry (Harmattan). This study area is a rain forest zone in the tropical region of the south western area of Nigeria covering an area of approximately 4,000 square kilometers. The major occupation of the people in the area is farming as Nigeria is a country with very rich cultural background in agricultural practices, rain-fed farming. Oyo state is bounded by Ogun, Kwara, Osun and Ekiti State, in the South, North, West and East respectively. The State has thirty-three Local Government Areas (33 LGAs) of which the study area which is Oluyole LGA is one among the LGAs of the State with population of 203,461 both male and female (NPC, 2006). There are 10 wards in Oluyole LGA and these wards divided into two sectors, namely, Idi-Ayunre Sector and Olode Sector.

Sampling Size

The population of the study consisted of all the youths' male and female in the selected communities or villages which made up of Oluyole Youth Council in Oluyole Local Government Area of the State.

Data Collection and Analysis

Data were collected only from among the youths' both male and female of oluyole youths' council for the study with a set of well-structured and validated questionnaire schedule with items based on the objectives of the study. Items discussed were centered on the specific objectives of the study. Trained extension officers were used to assist in the interview and administer questionnaire for data collection in the study areas. Descriptive statistic was employed to analysis the data gathered from the respondents. Descriptive statistic such as frequency distribution, Percentages, means and standard deviation was used to explain the socio economics characteristic of the respondents. Independent variable that was measured included in socio economic characteristic of respondents such as age, sex, religions, level of education etc. level of participation of youths' in community development activities was measured on a four-point rating scale of Highly Active (HA); Moderately Active (MA); Active (A); and Inactive (I).

RESULTS AND DISCUSSION

Socio-economic characteristics of the respondents;

Tables 1 revealed that many (56.4%) of the respondents were male while 43.6% were female. This indicates that the both male and female youths in the study area were fairly represented in the study. However male youths who took part in the study were slightly more than female youths. This finding concurs with Mukarumashana *et al.* Youths generally need proper harnessing so that they can maintain reliable status quo in their locality. It is easier for them to speak with one voice when they are brought together. This is why mobilisation yields progress. The entirety of youths in both urban and rural areas needs to be mobilized for proper impact to be felt in their communities (Adesope, 2007).

Age of respondents

Many (51.8%) of the respondents as shown in Table 1 were aged between 26-30years, 19.1% were aged between 31-35years while 15.5%, 12.7% and 0.9% of the respondents were aged between 20-25years, 36-40years and 41-above respectively. The sex distribution gave room for a balanced opinion from both sexes of the respondents and going by definition of youth as a person aged between 12 and 30 years by the Vision 2010 Report (2005).

Marital Status of respondents

Table 1 revealed that majority (64.5%) of the respondents were married while 35.5% were single

Religion of the respondents

50.9% of the respondents were Christians while 49.1% were Muslims. This implies that the respondents are evenly distributed across the two religions.

Level of Education of respondents

Table 1 show that majority (60%) of the respondents had secondary level of education, 31.8% had tertiary level of education, while 6.4% had primary level of education and 1.8% had no formal education. Findings clearly shows that majority of the youth had at least acquired basic education. Also the finding implies that a high percentage (secondary plus tertiary level) of the respondents was literates and could give relevant information on the subject matter.

Occupation of the respondents

Table 1 indicates that 43.6% of the respondents were artisans, 12.7% were civil servants, 10.9% were engaged in farming activities, 10.9% were students while 9.1% were engaged in teaching and 13.6% did not have any specific occupation. This implies that most of the sampled youths were artisans.

Source: Field survey 2018.

Organization type of respondents

Majority (80%) of the respondents as shown in Table 1 below belong to Oluyole youth organization, 1.8% belong to Youth amiable organization, 1.8 belong to Youth enlightment forum while 0.9% belong to Tokolase ladies club, RAHIS, Ifedola youth of Adungbee respectively and 13.6% did not have any specific the organization type. The importance of the youths to national development is without doubt because the various programmes directed at them by government at various times gives credence to this (Agumagu et al., 2006).

Year of being in an Organization

Table 1 show that 58.2% of the respondents have joined the organization between 4-6 years while 38.2% and 3.6% had joined the organization between 1-3 years and 7-9 years respectively.

Level of Youths' Participation in CDA;

Table 2 below revealed the level of youths' participation in community development (CD)

ISSN: 2814-0508

activities. The results show that punctuality to community development activities is ranked 1st with mean score (3.65). This might be as a result of the fact that majority of the respondent are literates and also married which makes them have regards for punctuality. Attendance of CD meetings was ranked 2nd, association participation in CD activities and association partnership with other association in carrying out CD activities were ranked 3rd while participation in CD activities was ranked 5th. Participation helps youths in planning and acting together for the satisfaction of their felt needs through organized efforts to acquire skills and the concepts required for their effective participation in the problem solving process (Jibowo, 1992; Akinbile et al., 2006).

Factors Associated with Youths' Participation in CDA

Table 3 below revealed the factors associated with of youths' participation in CD projects. The results show that Technical Know-how about the activities was ranked 1st with mean score (4.48) this might be as a result of majority of the youths' being educated. Collaboration with members was ranked 2nd with mean score (4.11) while level of awareness, assigned responsibilities and challenges during and after the activities were ranked 3rd, 4th and 5th respectively with mean score 3.75, 3.47 and 3.35.

The constraints of youths' participation in community development activities;

Table 4 shows the constraints of youths' participation in community development activities. The data below revealed that negative effects of traditions (mean score = 5.70) was ranked 1st. This implies that a community development activity was believed to have negative effects on tradition and culture of the people, thus limiting youths' participation. Poor monitoring (mean score = 5.60) was ranked 2nd, poor team spirit (mean score = 4.80) was ranked 3rd while unemployment (mean score = 4.10) and level of awareness (mean score = 3.97) were ranked 4th and 5th respectively.

SUMMARY

Majority of youths' participated in the community development activities of the study area were in their active year of age with average age of 30 years; many of them had secondary school education which makes them to participate actively in community development activities such as planning, initiation, implementation and evaluation stages. Poor funding, inadequate sensitization, inadequate awareness, improper implementation of activities, government policy, political instability was the major constraint which make some of the youths' not to participate actively in the community development activities.

CONCLUSION AND RECOMMENDATION

Youths generally need proper harnessing so that they can maintain reliable status quo in their locality. This study indicates that both male and female youths in the study area were fairly represented in the study. The average age of respondent in this study is 29.5 approximately 30 years of age, which means that the respondents were young enough to participate in the development activities in their areas. The youths' in the area contribute meaningfully in the initiation, planning and implementation of various activities going on in their community. Some of the respondents were married which enable them to know the gravity of team work spirit. Findings clearly shows that majority of the youth had at least acquired basic education. Also the finding implies that a high percentage (secondary plus tertiary level) of the respondents was literates and could give relevant information on the subject matter. Majority of respondents were self-employed which gives room for higher participation in CDA because they were independent people. Majority were in one organization or the other before coming together and formed the youths' council which give room for some of them having experience of unity, target and spirit of development of their community.

Table 4: Constraints of Youths' participation in community development activities

	Very High Freq* (%*)	High Freq* (%*)	Low Freq* (%*)	Very Low Freq* (%*)	Undecided Freq* (%*)	Mean Score	RANK

Source: Field survey 2018, Freq*= Frequency, %* =Percentage

The fact that majority of the respondent were learned, married and self-employed makes them to participate actively, effectively and efficiently in the community development activities in the area of study. Collaboration with others in the community made a meaningful impact in the community development activities through robbing minds together make them to achieve greater high of community development activities in their community. However, unemployment, problem of

ISSN: 2814-0508

insufficient fund, gender bias, poor team spirit, communication problem, poor level of awareness, political instability all these hinder the progress of development activities in the community which made some of the youths' not to part take in such activities.

Recommendations

1. Youths' should be motivated and encouraged to be more serious and have stable mind to learn, emulate, and ability to be a good leader, coordinator, supervisor, in order to be useful to their community.
2. Greater efforts should therefore, be geared towards encouraging the rural youths to be organized into groups so as to facilitate development of their community to greater high through both governmental and non-governmental agencies.
3. Responsibility should be assigned to youths' in order to know their level of competence, experience and leadership quality.
4. Young one should be encouraged and be carried along to see how their elder are doing thing so as to be moved and encouraged in order to have the mind of community development whenever they attained such age in life.
5. Local leaders should be educated on attribute of youths' as regards their participation and involvement in community development activities which has nothing to do with culture, norms and belief of the area.
6. Community leader should be sensitized on the role, importance and participation of youths' in the development of community.
7. Government should encourage youths on education and other apprentice work in order not to joined bad wagon, because ideal hand is devil workshop.
8. Provision of social amenities and infrastructural facilities such as good roads, stable electricity, and drinkable water, rehabilitation of school and construction of new building where necessary for the community.
9. The stakeholder should be encouraged to take active role in the development of the area where situated.
10. Provision of employment for the youths' in the area.
11. Empowerment scheme for youths' in the area should be organized.

ABSTRACT

Access to credit facilities has been identified as the direct solution to increasing investment in agriculture in Nigeria. To improve people's lives substantively, there is need to enable the poor to have access to credit and financial services which will be based on empirical findings that indicate basic financial services such as savings, credit, money transfer and insurance. This study assessed the impact of Village Alive Development Initiative on assets acquisitions among beneficiaries in Kwara State, Nigeria. A total of 319 beneficiaries were selected for the study using multi-stage sampling procedure. Primary data were collected using well-structured questionnaire, Descriptive statistics and Pearson Product Moment correlation (PPMC) were used for data analysis. The results of PPMC show that high loan rate (0.035), bank systems (0.040), tractor for land preparation (0.032), inadequate irrigation facilities (0.001) and little training/workshop (0.042) at $p<0.05$ were the factors that significantly influenced the growth in beneficiaries' enterprises and the constraints they are faced with. This implied that VADI beneficiaries are more informed now that agriculture should be seen as agribusiness and not just a leisure, hence, reliance on family labour should be shunned. The study concluded that VADI programme has helped in improvement of saving culture and high purchasing power of the beneficiaries. It was recommended that government policies more like VADI should be put in place to alleviate poverty

Key words: VADI, beneficiaries, constraints, assets acquisition, purchasing power

INTRODUCTION

One of the factors attributed to a declining productivity of the agricultural sector is farmers' limited access to credit facilities (Oruonye and Musa, 2012; Etonihu *et al.,* 2013). Access to credit facilities has also been identified as the direct solution to increasing investment in agriculture in Nigeria. Credit is a vital factor in agricultural production and in many cases may be limiting factor in small-scale agriculture especially in Nigeria (Salami and Aramowo, 2013). The small scale rural farmers' need for credit is more acute because their access to finance is lowered by their low productivity and wide spread poverty in the rural farm sector. The idea of enabling the poor to have access to credit and financial services is based on recent empirical findings which indicate that basic financial services such as savings, credit, money transfer and insurance can make a substantial positive difference in improving poor people's lives (Mahember, 2001; Dupas and Robinson, 2013). OECD (2010) contends that providing access to credit and financial services will stimulate the independence and self-development of poor households and micro-entrepreneurs. This will improve poor people's economic condition and their quality of life in the face of numerous uncertainties. Access to finance and financial services determines the capacity of an enterprise in a number of ways, especially in the choice of technology, access to markets, and access to essential resources which in turn greatly influence the viability and success of a business (Wole, 2009). He further states that securing capital for business start-up or business operations is one of the major obstacles every entrepreneur faces particularly those in the MSMEs sector. According to Sacerdoti (2005), among the reasons for lack of access to credit in Sub-Saharan Africa are SME‟s inability to provide accurate information on their financial status, lack of collateral, high loan default ratio, high cost of credit, and weak legal and judicial systems. Others include, long physical distance to the nearest financial services provider, lack of infrastructure and socio-economic and demographic characteristics that make them less creditworthy. Indeed, most small and mediums enterprises are unable to provide the needed collateral to support any large scale borrowing. Gaining access to credit and financial services is therefore a critical step in connecting the poor to a broader economic life and in building the confidence for them to play a role in the larger community (Dzisi and Obeng, 2013). It is assumed that credit will be used for productive purposes and would generate additional income for borrowers. Thus, the provision of credit came to be perceived as an important mechanism for reducing poverty (Stewart *et al.,* 2012).

Objectives of this study were to: examine the effect of VADI loan on assets acquisitions among beneficiaries; identify the constraints to the VADI programme; examine the relationship between growth in assets acquisition and challenges faced by the beneficiaries.

MATERIALS AND METHODS

Kwara State situated in the Savannah region of Nigeria. The region is characterized by favourable weather with annual rainfall of 400-1400mm (LNRBDA, 2015). As a result of this, the zone has a great potential for food production as farming is the predominant occupation of the people in the region, where farmers grow crops like maize, cassava, rice, sweet potatoes, soybean, sorghum, egg-plant, okra, water melon, Corchorus etc. The study area for this study consisted of Ifelodun and Ilorin South Local Government Areas (LGAs) of Kwara State. Multi stage sampling procedure was employed for the study. The first stage was stratified selection of seventy 70% of the community groups (Falokun-Oja, Apa-Ola, Elerinjare, Igbo-Owu, Omomere-Oja, and Ilota) that were involved in the VADI programme. The second stage is selection of 75% credit groups in the selected communities while the third stage involved selection of all the beneficiaries in the communities that were pre-selected (Table 1). Questionnaire was used to collect primary data for the study. Frequency distribution, percentages, mean scores and Pearson's Product Moment Correlation (PPMC) were used for data analysis.

Table 1: Sampling Procedure and Sample Size

Selected communities	Total number of credit group	75% percent credit group selected	Total number of participants
Falokun-Oja	5	4	65
Apa-Ola	5	4	50
Elerinjare	4	3	61
Igbo-Owu	5	4	47
Omomere-Oja	3	2	33
Ilota	6	5	63
Total	**28**	**21**	**319**

RESULTS AND DISCUSSION

Assets Acquisitions among Beneficiaries

The results showed that beneficiaries have more access to food stuff (M=2.44), they experienced increased savings (M=2.43), access to farm inputs (M=2.07), increased income (M=2.14), access to fertile land for cultivation (M=2.29), available market for produce (M=2.09), access to health care facilities (M=2.00), payment of children school fees (M=1,95) and entrepreneurial knowledge & skill competency (M=1.89). Considering financial assets VADI has contributed moderately to increased income (73.4%) and purchase of building material/rent (71.2%). On physical assets, purchase of transport for product distribution (61.4%), on social assets, there has been more network and contact with other entrepreneurs, on human assets, there has been more access to education (80.9%) and on natural assets, there has been more access to irrigation facilities (79.6%) and safe drinking water (69.6%). Also, there were high contributions to saving to meet basic needs (50.8%), purchase of food (48.2%) and more access to food stuffs purchase (48.2%) among beneficiaries. However, in the purchase of electronic, payment of utility bills and purchase of television, 63.8%, 74.3% and 85.9% respectively were indifference as regards the contribution of VADI. The results shows tremendous effect on the financial, physical, social, human and natural assets as they were all shown to have positive increase in the lives of the beneficiaries. The whole effects/benefits that VADI members had derived from the programme cannot be overemphasized. The beneficiaries now enjoy those benefits that they had no or little access to before the advent of the programme. However, the least ranked benefit was the access to family labour (MS=1.02). The implication of the above was that VADI has made the farmers understood that agriculture should be seen as agribusiness and not just a leisure hence, reliance on family labour should be exiled and the beneficiaries are advised to employ hired/paid labour to work on their farm.

ISSN: 2814-0508

OECD (2010) contends that providing access to credit and financial services will stimulate the independence and self-development of poor households and micro-entrepreneurs.

Table 2: Distribution of the Beneficiaries by their Assets Acquisitions

Contributions of VADI to Assets Acquisitions	No contribution (%)	Indifferent (%)	Moderately contributed (%)	Highly contributed (%)	Mean score	Rank
Financial Assets						
Income		20 (6.3)	234 (73.4)	65 (20.4)	2.14	4
Saving to meet basic needs		24 (7.5)	133 (41.7)	162 (50.8)	2.43	2

Constraints faced by VADI Beneficiaries

Constraints encountered among respondents were in the size of loan available to the farmers (48.3%) that was too small, delay in bank deposit (30.4%) and terms of repayment which was very short (27.6%). However, few respondents (15.7%) agreed that there was delay in loan disbursement and high interest rate with 5.0% (Table 3). Mohan (2008) opined that agribusiness is seasonal and the inputs needed for the production should be made available before the cropping season is full blown so as to ensure optimal yield from the production and return on investment.

ISSN: 2814-0508

Table 3: Constraints Faced by VADI Beneficiaries

Constraint	Frequency	Percentage (%)
High interest rate	16	5.0
Delay in the disbursement of loan	50	15.7
Delay in bank deposit	97	30.4
Terms of repayment very short	88	27.6
Uncultured behavior of VADI officers towards client	21	6.6
Loan size too small	154	48.3

Source: Field survey, 2019

Relationship between growth in assets acquisition and challenges faced by the beneficiaries.

The result in table 5 indicates the Pearson Product Moment Correlation (PPMC) analysis showing relationship between growth in beneficiaries' enterprise and their level of constraints. The finding revealed that there were significant relationships between constraints to enterprise growth and high loan rate (**r** =0.035), bank system (**r** =0.04), tractor for cultivation (**r** =0.032), inadequate irrigation facilities (**r** = 0.001), inadequate shea butter facilities (**r** = 0.017) and little training /Workshop (**r** = 0.042).

Table 4: Correlation Analysis between the Growth in Beneficiaries' Enterprise and their Level of Constraints

Variables	r – value	Remark
High loan rate	0.035	Significant
Bank systems	0.040	Significant
Tractor for cultivation	0.032	Significant
Inadequate irrigation facilities	0.001	Significant
Inadequate shea butter facilities	0.017	Significant
Little training /Workshop	0.042	Significant

Source: Field survey, 2019

CONCLUSION AND RECOMMENDATION

The study concluded that VADI scheme has helped in increased assets acquisition of the beneficiaries. However, the programme is faced with challenges in the size of loan available to the farmers which was considered to be too small, delay in bank deposit and the bottleneck of timely disbursement due to banking system. Therefore, the following recommendations were made:

- Government policies more like the VADI intervention should be promoted to enable the farmers improve on their assets acquisition.
- More farmers' cooperative groups should be encouraged to ensure that their members are taken care of and reduce reliance on the government.
- There should regulation policy to ensure loan is made available to farmers at the right time and lowest rate to ensure maximum production.

AWARENESS OF ICT IN INFORMATION TRANSFER AMONG COFFEE FARMERS FOR SUSTAINABLE PRODUCTION IN KOGI STATE

*Ogunjobi T.E., Famuyiwa B.S., Awodumila D.J. and Agbebaku, E.E.O.

Cocoa Research Institute of Nigeria, Ibadan, Oyo State

ABSTRACT

The study investigated awareness of ICT in Information transfer among coffee farmers for sustainable production in Kogi State, Nigeria. The population of the study consisting of 71 coffee farmers in three local governments. Seventy-one pieces of questionnaire were administered with 61 returned rates making 87.14%. The questionnaires were analysed using descriptive analysis (frequency counts and percentages). The study revealed that radio, phone and television are the common ICT gadgets available for use by coffee farmers in Kogi state while projector, computer, GIS are rarely available. The study therefore recommended that Federal government should provide soft loans to acquire those ICT facilities that are not available for farmers to be able to be at par with their counterpart in developed world and also to enjoy benefits that comes with the usage of ICTs tools in solving famers problems. This will indirectly improve standard of living and increase productivity of coffee farmers in Nigeria.

Key words: ICT, Information transfer, Coffee farmers, Kogi State, Awareness

INTRODUCTION

Information and Communication Technology (ICT) is defined by the World Bank as any device, tool or application that allows the exchange or collection of data through interaction and/or transmission. It includes anything ranging from radio to satellite imagery, mobile phones or electronic money transfers. The application of ICTs in agriculture is often regarded as e-agriculture (FAO, 2020). The power of ICT in this era has opened new channels of knowledge management that could play vital roles in meeting the dominant challenges related to sharing, exchanging and disseminating knowledge and technologies. Today ICTs have been recognized as a key agent in changing the agricultural and knowledge services. More so, farmers (Coffee farmers inclusive) could access relevant information through ICT at any point in time, and this enables them to create jobs with development agencies and other farmers, and ultimately yield higher agricultural productivity (Ramli *et al*., 2015, Abdullah and Samah, 2013). These claims were supported by Kale *et al*. (2015) that ICT provides timely information on what, when, where, why and howssss to produce and sell agricultural products. Furthermore, ICT-based market information systems have a proven track record for improving the rural livelihoods in middle income earners of developing countries where they have been introduced. These findings are consistent with De Silva and Ratnadiwakara, (2008) who found that there is likelihood of reductions in business cost with the use of ICT. The use of ICT enables farmers to access appropriate and current information in agriculture. This provides likelihoods for younger generation-agro based entrepreneurs to established their own network and websites regardless of time and place (Bhalekar *et*. *al*., 2015; Pande and Deshmukh, 2015; Ramli *et al*., 2015; Singh *et al*., 2015a; Singh *et al.,* 2015b). Consequently, they could publicize their goods both in national and international markets. This assertion is in accordance with Bhalekar *et*. *al*., (2015) that ICT could be used to secure food traceability and reliability that has been an emerging issue concerning farm products and diseases. Besides, new agricultural and rural business such as e-commerce, real estate business for satellite offices, rural tourism, and virtual cooperation of small-scale farms are initiated. Similarly, Yimer (2015) indicates that ICT furnish up-to-date knowledge and information on agricultural technologies, best practices, markets, price trends, and weather conditions.

The areas in which ICT can be deployed in coffee farming are: online services for information on coffee. online interaction facility to interact with nearest research station like CRIN, agriculture and allied departments for advice on current schemes, projects, varieties etc. Information on all sources of agricultural credit and crop insurance and their terms and conditions. Information sharing mechanisms among coffee farmers, extension workers and researchers. Online information on market prices of coffee, online monitoring and information sharing on all agricultural development projects in the country, online weather forecasting and its impact on coffee, on a weekly basis, including early warning systems. E-commerce through connections between traders, retailers, and other farmers. Information on availability and rates of agricultural inputs on coffee seeds, fertilizers, pesticides, machinery etc. and on all governmental and non-governmental organizations working directly or indirectly in the agricultural sector. The ICT devices that help facilitating farming activities include radio, television, cellular phones, computers, tablets, hardware and software, satellite systems (Munyua and Adera 2009; Pande and Deshmukh 2015). In the same way, (Yimer, 2015; Munyua and Adera 2009) reports that radio is extensively used to inform users on agricultural topics, including new and upgraded farming techniques, production management, and market information. According to Ramli *et al*, (2015), ICT is an effective solution to problems that militate against the development of agricultural industry, such as weak marketing linkages, poor information management, low productivity, low income and lack of diversity. Hence it is imperative to keep the farmers with lucrative and remunerative agriculture through ICT. In this context new and advanced ICT tools such as internet and mobile phones have great potential to facilitate technology transfer to farming community. Through ICT tools, people in rural areas can connect with the local, regional and national economy and access markets, banking/financial services and also farm based services.

Objectives of the Study

The major objective is to find out the awareness of ICT in Information transfer among coffee farmers in Kogi State, Nigeria. The specific objectives are to:

1. Find out types of ICT available for use by coffee farmers in Kogi State, Nigeria
2. Investigate the accessibilities of ICT facilities by coffee farmers in Kogi State, Nigeria
3. Find out sources of awareness of ICT usage among coffee farmers, Kogi State, Nigeria.
4. Determine benefits of using ICT in coffee farming

Research Questions

1. What are the types of ICT facilities available for use by coffee farmers in Kogi State?
2. Where do you access ICT facilities?
3. What are the sources of awareness of ICT usage among coffee farmers in Kogi State?
4. What are the benefits of using ICT facilities in coffee farming?

MATERIALS AND METHODS

Coffee farmers in Iyamoye, Kogi state were investigated. 71 pieces of questionnaire in three local governments were administered and 61 returned making 87.14% Returned rate. Returned questionnaire were sent for analysis and interpretation of data using descriptive analysis such as frequency counts and percentages.

RESULTS AND DISCUSSION

In Table 1, ICTs available for use by coffee farmers at Iyamoye are radio 26 (42.6%) which carried the highest number, followed by phone 14 (23.0%), also cassette 8 (13.1%), E-bulletin 7 (11.5%), and GIS and projector carried the least 2 (3.3%). This is supported by Yimer, 2015; Munyua and Adera 2009 who reported that radio is extensively used to inform users on agricultural topics, including new and upgraded farming techniques, production management, and market information. Khattar, (2017) also stated that ICTs are now being used by farmers to disseminate farming activities across the globe.

From the Figure 1 below, Coffee farmers access ICT majorly from workplace which is their farm and home. This means ICTs facilities used by Iyamoye farmers were used mostly for their farming activities. This is supported by Bhalekar *et. al*. (2015); Pande and Deshmukh, (2015).

ISSN: 2814-0508

Table 1: Types of ICT facilities available for use by coffee farmers in Kogi State

ICT facilities	Rarely Available	Moderately Available	Available	Not Available
Radio	12 (19.7%)	15(24.6%)	26 (42.6%)	8(13.1%)
Television	7(11.5%)	16(26.2%)	11(18.0%)	26(42.6%)
Phone	17(27.9%)	16(26.2%)	14(23.0%)	13(21.3%)
Computer	55(90.2%)	2(3.3%)	4(6.6%)	60(98.4%)
Cassette	49(80.3%)	4(6.5%)	8(13.1%)	60(98.4%)
Recorder	51(83.6%)	4(6.6%)	4(6.6%)	2(3.3%)
GIS	57(93.4%)	2(3.3%)	1(1.6%)	1(1.6%)
Projector	58(95.1%)	2(3.3%)	1(1.6%)	0%
E-bulletin	41(67.2%)	7(11.5%)	6(9.9%)	7(11.5%)

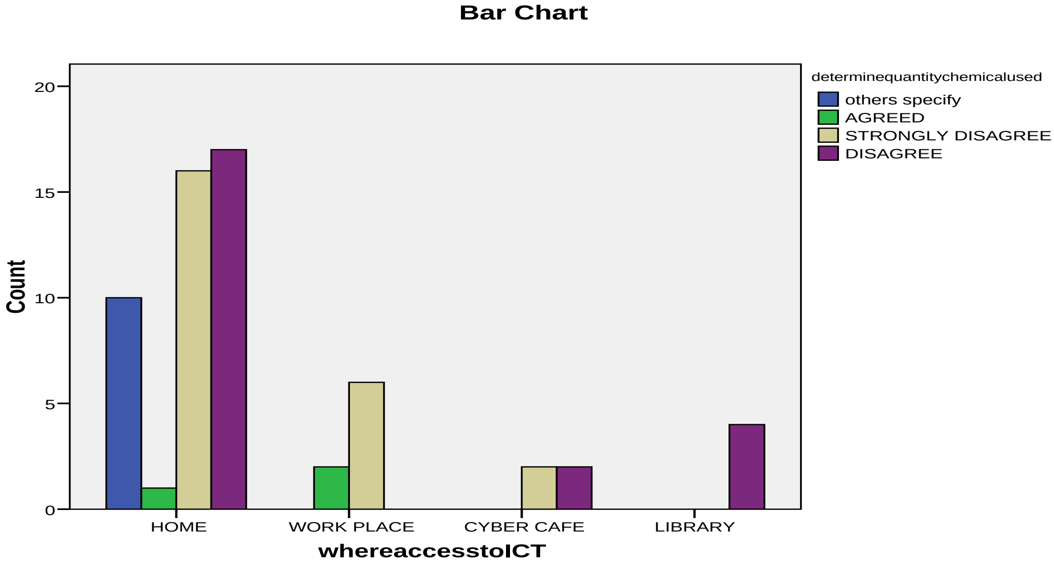

Figure1: Farmers' accessibility to Information Communication Technologies (ICTs)

Table 2 revealed sources of awareness of ICT tools among coffee farmers in Kogi State, the table revealed that CRIN (60.7%) carried the highest percentage, extension agents (16.4%) and NGOs (11.5%). It can be inferred from here that despite paucity of research fund Cocoa Research Institutes of Nigeria is performing her duty of reaching out to all farmers in Nigeria. Which means all mandate crops are being touched especially, coffee. Also, extension agents from CRIN are performing their roles of reaching out to coffee farmers at Iyamoye, Kogi state in particular.

Table 2: Sources of awareness of ICT among coffee farmers in Kogi State

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	EXTENSION AGENT	10	16.4	16.7	16.7
	CRIN/ RESEARCH INSTITUTE	37	60.7	61.7	78.3
	NGOs	7	11.5	11.7	90.0
	FARMERS ORGANIZATION	6	9.8	10.0	100.0
	Total	60	98.4	100.0	
Missing	System	1	1.6		
Total		61	100.0		

The following are the benefits of using ICT among coffee farmers in Kogi State (Table 3): Increase productivity (52.2%), saves time (34.4%) and reduction of risk (11.5%). These claims are supported by Ramli *et al.* (2015) and Abdullah and Samah, (2013), that farmers (Coffee farmers inclusive) could access relevant information through ICT at any point in time, and this enables them to ultimately have higher yield of agricultural productivity. Also, these claims were supported by Kale *et al.* (2015) that ICT provides timely information.

Table 3: Benefits of using ICT for Information Transfer in Kogi State

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	SAVES TIME	21	34.4	35.0	35.0
	INCREASE PRODUCTIVITY	32	52.5	53.3	88.3
	REDUCE RISK	7	11.5	11.7	100.0
	Total	60	98.4	100.0	
Missing	System	1	1.6		
Total		61	100.0		

CONCLUSION AND RECOMMENDATIONS

It was discovered that coffee farmers in Iyamoye Kogi state still lack behind in using ICT in transferring information. That is low level of use of ICT among coffee farmers, this indirectly must have led to low productivity. It was also discovered that few that have this ICT do not know the benefit of using it, hence they lack ICT knowledge. Based on the above discovery, it is therefore recommended that:

1. Since availability does not connote usability, ICT training should be organised to coffee farmers in Iyamoye. This will help the farmers to learn how to use the available ones profitably.

2. Regular visit of extension officers is needed so as to always remind them the importance and usage of ICT facilities in their farming activities.

3. Special recognition and ICT subsidy loan should be provided by government for coffee farmers in Iyamoye. This will help them in purchase of these ICTS that are not available as it has been discovered that benefits of it will improve the standard of living of coffee farmers, improve productivity and increase food production in Nigeria.

4. Therefore, since this study found that ICT has a low level of use among coffee farmers, it infers that taken into cognizance all the benefits of use of ICT as earlier explained, there is urgent need by coffee farmers in Kogi state to start using ICTs so as to increase output. Special recognition and ICT subsidy should be given to coffee farmers so as to boost ICT use.

ABSTRACT

Covid-19 pandemic has shifted organisation's such as research institute libraries activities to less of physical engagement as measures especially social distancing are to be ensured for safe practices in the libraries. Researcher's information needs which is always enormous and current demands that opportunity for contact is maintained by libraries and researchers. This demands library services needs to be transformed digitally through the deployment of digital tools. Digital transformation of the library services ensures convenience and ease of access by the researchers. This is imperative for effective productivity as accesses to information increases innovation in agricultural practices. It is required of the research institute to provide adequate funding for the acquisition of digital tools and opportunities for staff training to ensure the digital tools are deployed effectively in a bid to achieve the library goals and objectives even admist the Covid-19 pandemic.

Key words: Covid 19, Digital tools, Digital transformation, Agricultural research institutes, libraries

INTRODUCTION

Coronavirus disease (Covid-19) pandemic is a novel virus that has been ravaging the whole world since it time of identification on 31st December, 2019 in Wuhan, Hubei city of China (WHO, 2020). It spread did not affect only developed countries but as well as developing country such as Nigeria. The Covid-19 virus is a virus that can spread quickly, highly contagious with high mortality rate compare to other contagious disease. Based on the recommendation of the World Health Organisation (WHO) in a bid to curtail it spread among people social distancing, lock down, quarantine and isolation are key things expected of countries, organisation, as well as individuals to abide with. Organisations, such as the agricultural research institute libraries with the sole responsibility of meeting the diverse and daily information needs of the library users, are expected to take the advantage digital tools offers in ensuring physical contact is reduced. Agricultural research institute as an organisation relevance in the era of the Covid 19 pandemic can be ensured through digital transformation. Covid 19 pandemic as pose a major challenge to accessing of information from the research libraries as certain measures had to be put in place specially to reduce the number of researchers that may want to use the library at a time in a bid to maintain social distancing as well as avoid crowding within the library. Thus, in a bid to ensure the research library being still consulted, there is need for the deployment of technological facilities for running library services leading to digital transformation of the library.

According to Mazurek (2019), digital transformation (DT) can be regarded basically as organisation change. This is implemented through the deployment of technological facilities in areas that includes operation models, models of cooperation regarding the internal and external environment, provision of services, technology used information management. Digital transformation involve library making use of digital technologies and its supporting features to provide opportunity for library users to relate, interact, collaborate with the library and gets the needed information without having the need to be physically present within the library. For the research community through digital transformation, there has been predominantly large number of information resources that are available online as well as opportunity for knowledge dissemination electronically. Digital transformation positions the library such as the agricultural research institute libraries to shift it services provision electronically by ensuring library services can be rendered online. Library services in which technology can be deployed into Webopac, digitization, building of institutional repository linked to the library website, social media pages on different platforms, electronic referencing, selective dissemination of information, document delivery and much more. The implementation of such service will increase the confidence of researcher to see the relevance of the library especially in during this pandemic era of Covid-19.

The uptake of digital technologies to mediate human interaction, digitization of print documents and opportunities to have a personalised channel such as email, social media pages have provided avenue for library to leverage in the satisfaction of diverse information needs of the library users especially in this era of Covid-19 where physical contact is expected to be minimal. There is therefore need for the library to acquire digital tools as well train staff to effectively use the digital tools to promote digital transformation of the research libraries.

According to Verhoef et al (2019) digital transformation is driven by three predominant factors. First, the wide entrance of the World Wide Web (WWW) as well its acceptance and use globally, including a significant number of accompanying technologies such as SEO, Web 2.0, smartphones, broadband internet speech recognition, cloud computing, crypto currencies, Internet of Things (IoT) and online payments platforms) which have increased sporadically and have given opportunity for activities to be done electronically. Second, change in competition dramatically due to the presence of new technologies. As regards library being the provider of relevant information, for examples internet and web sites providers, telecommunications operators; E-journals and E-book providers and so on are trying to take the advantage of the web to provide information and reduce the patronage of the library for needed information. Third, the behaviour of the consumer such the library clientele is changing as a response to the digital revolution.

Digital transformation and innovation in digitization are made possible by digital technologies and are boosted by researchers' expectations, as well as by prospects of greater economic and social benefits. Successful digital transformation comes not only from implementing new technologies but also from transforming organizations to take advantage of the possibilities that new technologies provide, and requires digital resources. Major digital transformation initiatives are centered on re-envisioning customer experience, operational processes, and business models (Kohli and Melville, 2019)

There are many external factors forcing transformative change in libraries, such as shifts in scholarly communication and how research is published and disseminated, technology that allows users to access information without intermediation, user demands for access to new types of scholarly information (e.g. data sets, multimedia resources), and accelerated globalization. Learners and researchers have new demands due to the complexities of blended learning, experiential learning, distributed learning and the concomitant need for mobile content delivery, increased focus on research data management and data mining, and increased options for disseminating research (Anuradha, 2018).

DIGITAL TRANSFORMATION AND LIBRARY SERVICES IN AGRICULTURAL RESEARCH INSTITUTE IN NIGERIA

Digital technologies can be employed to facilitate the following services within the library.

1. **Web-OPAC:** The catalogue of a library provides access to the holdings of a library. Through the catalogue library users can search for information materials to determine if it available within the collection of the library. Web OPAC (Online Public Access Catalogue) allows the library to host her catalogue on the web there by ensuring access is provided from any location and at any time. Researchers then have the opportunity to determine if a particular information material they intend to consult in the research library is available, through checking the Web OPAC of the institute online. This will help a researcher to be sure that a particular resource he or she intend to consult is available or not, thereby avoiding the risk of exposure to crowd as well as saving time and cost.
2. **Digitisation:** This can be regarded as the process of converting print information material into electronic readable format. Digital tools such as scanner and necessary software on the computer system can be used. It ensures that information materials that are available in print format needed by library are digitised for access electronically.
3. **Web 2.0:** This is associated with web applications that facilitate participatory information sharing, inter-operability, users' centred design and collaboration on the World Wide Web (Verma and Verma, N.D). Furthermore, with. Web 2.0, the holdings of the library become virtual collection and library become without wall. Library use the Web 2.0 in a bid to share information and receive feedback from thereby building knowledge as understanding is sustained in a real time. Such tools that facilitate this real time communication includes blogging, social media, wikis, multimedia sharing, audio blogging and pod

casting and so on. Library service that can be well integrated is reference service as two ways communication must be sustained between the librarians and the library users.

4. **Selective Dissemination of Information (SDI):** This is an activity of the library, in which the librarians seek to understand and determine the information needs of the various researchers of the library based on their research area, topic of interest and so on. The researcher's profile is generated by making a list of needed information to be filled by the researcher and sent to their mail. Availability of information materials that matches the areas of the researchers are also delivered electronically.
5. **Institutional Repository:** Institutional repository is a service-based activity of the library in which research breakthroughs (findings) generated by staff and researchers of research institute are presented in seminars, symposium and workshops. These information resources are captured and stored on the library website for wider access and use by information seekers. Such information resources are presented in portable document format (PDF) and stored on the institutional repository. The institutional repository serves as back up for archiving the seminar presentation. Publications of the staff and researchers belonging to the research institute are stored in the repository of each institute.

CONCLUSION AND RECOMMENDATION

Agricultural researchers are individuals whose contributions are important to sustainable practices of agriculture in nations of the world such as Nigeria. Researchers need access to current information in order to be aware of new practices for improvement int agricultural practices globally and how they can implement it locally as well as contribute their own findings, such information are contained in the collections of the research libraries.

Covid 19 pandemic has changed the way information is being accessed as there is need for less physical gathering. Therefore, engineering information services provision through digital technology is key to ensuring the consultation of the research libraries in Nigeria. Leading to better and sage information service provision of the library and improved agricultural practices in the nation at large.

In a bid to achieve digital transformation for research library service provisions, the following recommendations shall be made.

1. Improvement in library personnel training through exposure to current trends in library practices, ICT based services provision and much more. This will ensure research librarians are abreast of development in library practices and how they can implement it in their library especially in Covid 19 pandemic era. Likewise, opportunities for havd on experience with digital tools increases the potential of it being deployed in the research library settings

2. Provision of funds for the acquisition of digital tools needed to ensure effective and efficient digital transformation in the research library.

AWARENESS AND COPING STRATEGIES TO COVID-19 PANDEMIC BY COCOA FARMERS IN ONDO STATE OF SOUTHWESTERN NIGERIA

Agulanna, F.T.

Economics and Extension Department, Cocoa Research Institute of Nigeria (CRIN), Ibadan, Oyo State
Corresponding author's e-mail: foluagu@yahoo.com

ABSTRACT

The study investigated the awareness and coping strategies to the COVID-19 pandemic by cocoa farmers in Ondo State of Southwestern Nigeria. Random sampling technique was used to select cocoa farmers in the study area. A total of fifty cocoa farmers (respondents) were purposively selected from Ile-Oluji/Oke-Igbo local government area. Information was collected from the selected farmers with the aid of well-structured questionnaires and the data retrieved from forty-six cocoa farmers collected were analysed with descriptive statistics and chi-square analysis. The result of the analysis showed that 76.1% of the respondents are above the age of 41 years, 78.3% are males while 76.1% are married. Similarly, 78.3% of the cocoa farmers have 4-6 children in the household, 26.1% had secondary education, 43.5% have 16 to 20 years farming experience while 73.9% lived in condominiums or housing units where residents are herded together thereby predisposing them to the risk of the contagion. Majority of the respondents (96%) were aware of the occurrence of corona virus, 69.6% of the respondents coped by relying on less expensive food during the lockdown, 56.5% reduced their food consumption due to income loss, 63% reduced the number of meals eaten daily while 67.4% reduced the portion or size of meal daily during COVID-19. The chi-square test also revealed that there is significant relationship between farmers' awareness and coping strategies to covid-19, the quality and type of food they consumed.

Key words: COVID-19 pandemic, Farmers' awareness, coping strategies, Ondo state, Nigeria

INTRODUCTION

Cocoa is one of the most important perennial tree crops grown in tropical climates around the equator. It is also a highly valuable economic tree crop because it provides employment and income to the farmers, raw materials for industries and foreign exchange for producing countries such as Nigeria (Afolayan, 2020). Here, it is worth noting that cocoa is a major cash crop of the tropical forest, most notably in West Africa where export earnings from its sales forms a major part of national economies (Mayhew and Perry, 1998). However, the matter of cocoa and Nigerian government's handling of it is both complex and bizarre, to say the least. To begin with, prior to political independence in 1960, agriculture was the mainstay of the Nigerian economy; it was also the major source of foreign exchange earnings for the country. However, the discovery of oil in the 1970s led to a shift of emphasis from the agricultural sector to petroleum. With particular reference to the cocoa economy, the undue dependence by government on oil has led to a decline in export-led growth coming from cocoa.

But it is not only government neglect that has hampered the cocoa industry in Nigeria. On the contrary, the decline in cocoa productivity has been exacerbated by other factors, a few of which are outlined below:

i. majority of cocoa farmers lack the technical know-how on modern methods of agricultural practices;
ii. most young people are unwilling to engage in farming or replace their ageing parents who are either incapacitated or weak to engage in farm work;
iii. there is mass exodus of farmers from rural to urban areas in search of the better life;
iv. there is high cost of agricultural labour, prevalence of pests and crop diseases;
v. most of the cocoa plantations are old while a majority of cocoa processing factories are decrepit, neglected and not functioning, and
vi. there is lack of incentives or financial aids to cocoa farmers, etc. (CRIN, 2003; Akinnagbe and Ajayi, 2010; Afolayan, 2020).

The factors highlighted above are not exhaustive. However, the point needs to be made, which is that the case with cocoa is not altogether that of gloom, misery or despair. On the contrary, even with the dependence on oil and the neglect of the agricultural sector by various Nigerian administrations, cocoa remains the major non-oil export that still generates high income for the country. This is the point made by Afolayan (2020), Akinwale (2006) and Ibiremo *et al.* (2011) when they averred that in Nigeria, cocoa is a key export crop with revenue of at least 34 billion derived annually from the export of cocoa beans alone, besides revenue from cocoa by-products like butter, cake, liquor and powder. Indeed, cocoa is only second to crude oil as the major revenue earner for Nigeria.

The contribution of cocoa to Nigeria's economy: a historical perspective

Nigeria ranks among the top six cocoa beans producers in the world. And as indicated already, after oil, cocoa is the country's most important agricultural export product. Indeed, cocoa is a household cash crop and key agriculture produce in Nigeria. Cocoa is consumed locally and also exported internationally to generate foreign exchange for the country. Statistics show that Nigeria produced 367,000 tonnes of cocoa in 2017, and that out of the 161,285.72 metric tonnes of agricultural produce exported, cocoa export alone accounted for 33,294 tonnes (NEPC, 2018). Again, the total income from non-oil products exported by Nigeria in 2019 was US$1,870.677 million; out of this, cocoa exports alone amounted to US$394.798million. No other agricultural export crop has contributed to Nigeria's GDP like cocoa. Besides being a major foreign exchange earner for the country, the cocoa sub-sector provides employment both directly and indirectly, to many youths in the country. Cocoa is also an important source of raw materials to many industries in the cocoa value chain in the country.

Historically, cocoa is said to have been first cultivated in the Delta region before spreading to Western Nigeria around 1890 where ecological conditions and the soil type encourages cocoa growing and cultivation. It is generally agreed that all the states in southwestern Nigeria are cocoa producing states, with the only exception being Lagos, which according to Afolayan (2020), does not produce cocoa in "commercial quantity." But of all the cocoa producing states in Nigeria, Ondo State is the largest with its output capacity of about 77,000 tons per annum (Oluyole, 2005).

The covid-19 global pandemic had a negative impact not only on the cocoa sub-sector but on the agricultural sector generally. In the main, the pandemic exposed many rural farmers to debilitating health problems, and by restricting human and vehicular movement, led to low agricultural productivity, which in turn led to low income for farmers and their households. It is common knowledge that the COVID-19 pandemic led to the collapse of many national economies. To minimize the impact on the livelihood of their citizens, many governments all over the world initiated various fiscal interventions to alleviate the suffering caused by the pandemic. But as with many government policies, in Nigeria, many households, micro, small and medium enterprises affected by COVID-19 did not benefit from the credit facility or stimulus package announced by the national government through the Central Bank of Nigeria in March, 2019. Usually too, rural farmers and their households are the worse off as neither government nor local authorities extend help or fiscal assistance to them in time of need. As with other cocoa producing states in Nigeria, cocoa farmers in Ondo state experienced great hardship during the peak period of the global pandemic. The pandemic did not only affect farmers' health or farming activities but also their livelihood. Hence, this study examined the coping strategies of cocoa farmers in Ondo state during the COVID-19 global pandemic. Well-structured questionnaires were administered to 50 cocoa farmers to collect primary data on farmers' socio-economic characteristics, awareness and coping strategies during the pandemic. The objectives of the study are: (i) to determine the socio-economic characteristics of cocoa farmers in the study area, and (ii) to identify the awareness and coping strategies of cocoa farmers in the study area during COVID-19.

MATERIALS AND METHODS

The study was carried out in South-western Nigeria, which is one of the six geopolitical zones in the country. Ondo state is one of the states in South-western Nigeria, made up of 18 Local Government Areas and the chief cocoa producing state in Nigeria. The state lies between longitudes 4"30" and 6" East of the Greenwich Meridian, 5"45" and 8" 15" North of the Equator. The state is bounded in the North by Ekiti/Kogi State; in the East by Edo State; in the West by Oyo and Ogun States and in the South by the Atlantic Ocean. Ile Oluji/Oke-Igbo LGA was purposively selected. Well-structured questionnaires were administered to fifty cocoa farmers in six villages/towns out of which forty-six were used for the analysis due to the fact that not all the questionnaires were completed. Data retrieved from the information collected was analysed with descriptive statistics and chi-square analysis. In the study, the null hypothesis and alternative hypothesis are generally stated as: Ho: No relationship between the awareness of cocoa farmers and their coping strategies during covid-19 pandemic.

ISSN: 2814-0508

H1: There is a relationship between the awareness of cocoa farmers and their coping strategies during covid-19 pandemic.

RESULTS AND DISCUSSION

Table 1 shows the socioeconomic characteristics of cocoa farmers in the study area during the pandemic. The table shows that 76.1% of the respondents are above the age of 41 years, 78.3% while males and 76.1% are married. Again, 26.1% of the respondents had secondary education, 43.5% had 16 to 20 years farming experience, 78.3% had 4-6 children in the household while 73.9% lived in condominiums or living conditions that brought people in close proximity to each other. Such living conditions are risk factors for the spread or transmission of COVID-19 since the possibility of contracting the contagion increases with contact or people sharing common facilities such as conveniences and rooms. It follows from the foregoing that because of their lifestyle and economic deprivation cocoa farmers are among the most vulnerable populations to COVID-19 pandemic.

CONCLUSION AND RECOMMENDATION

The study assessed the awareness and coping strategies to COVID-19 pandemic by cocoa farmers in Ondo State of Southwestern Nigeria. The findings showed that despite the long neglect that the cocoa sub-sector has experienced, cocoa has remained a resilient agricultural product, and one that has contributed immensely to the growth of the Nigerian economy. The findings further revealed that the impact of COVID-19 on farmers and farming activities was dire and grim. However, it is heartwarming that the cocoa industry was able to withstand the negative effect of the pandemic, which threatened to kaput the past efforts of committed individuals and governmental agencies. The cocoa sub-sector has remained vibrant and continues to contribute to the nation's economic growth and revival. To restore cocoa to the enviable state it occupied in pre-independent Nigeria, it is recommended that government, stakeholders and other concerned organisations make concerted effort to resuscitate cocoa production and marketing in the country. This way the nation's tottering economy will be revived and the country will regain its past economic glory.

ABSTRACT

The focal point of this study is to investigate Significance of Development Communication to Social change. Secondary method of data collection which entails the review of journals and publication related to the subject was adopted in data collection. Findings from the study revealed that the components of development communication were used in the implementation of projects and involved members in the implementation of the project. Absence of participatory communication in some of the projects did not help implementers understand the challenges the community goes through in maintaining such developmental projects thus come together to find solutions to them. By facilitating mutual understanding and by building trust among stakeholders, communication becomes of critical value in fostering participation and social change. The study therefore recommends that project planners should design and adopt appropriate development communication model towards sustaining projects for project implementers and communities so as to get the desired social changes that come with such projects.

Key words: Development communication, Social change, Social development, Significance

INTRODUCTION

Development communication refers to the use of communication to facilitate social development (Kamarah, 2011). Development communication engages stakeholders and policy makers, establishes conducive environments, assesses risks and opportunities and promotes information exchange to create positive social change via sustainable development. Development communication techniques include information dissemination and education, behavior change, social marketing, social mobilization, media advocacy, communication for social change, and community participation. Development communication has not been labeled as the "Fifth Theory of the Press", with "social transformation and development", and "the fulfillment of basic needs" as its primary purposes (Abiona, 2019). Jamias articulated the philosophy of development communication which is anchored on three main ideas. Their three main ideas are: purposive, value-laden, and pragmatic (Bella, 2013).

Chadha, D. (2015) expanded the definition, calling it "the art and science of human communication applied to the speedy transformation of a country and the mass of its people from poverty to a dynamic state of economic growth that makes possible greater social equality and the larger fulfillment of the human potential". Melcote and Steeves (2016) saw it as "emancipation communication", aimed at combating injustice and oppression. The term "development communication" is sometimes used to refer to a type of marketing and public opinion research, but that is not the topic of this article.

The emphasis on participation in development also implies increased attention to communication, because there can be no participation without communication. Communication is central to this task in many ways; thus, it enables planners, when identifying and formulating development programmes, to consult with people (the stakeholders) in order to take into account their needs, attitudes and traditional knowledge (Diouf, 2014). Development communication is the only way project beneficiaries can become the principal actors to make development programmes successful (FAO, 2016). Communication for Development (ComDev) or development communication can be defined as the planned and systematic use of communication through inter-personal channels, ICTs audio-visuals and mass media for social change. Development is about change, and if development initiatives of any kind are to be sustainable they should start with mechanisms that ensure broad participation by all those who have some interest in the intended change (Mefalopolus, 2018). In ComDev, rural people are at the centre of any given development initiative and so communication is used in this sense for people's participation and community mobilization, decision making and action, confidence building for raising awareness, sharing knowledge and changing attitudes, behaviour and lifestyles (FAO 2016). According to Adedokun et al. (2010), communication is expected to be used to facilitate community participation in a development planning initiative. The objective of this study is to investigate the significant of development communication to social change. The specific objectives are;

i. To determine is communication influence in sustaining development projects.
ii. To find out the importance of The use of Communication in Involving Communities in development projects.

Development Communication in Africa

The African school of development communication sprang from the continent's post-colonial and communist movements in the late 1960s and early 1970s. Anglophone Africa employed radio and theatre for community education, adult literacy, health and agricultural education (Kamlongera, 2013, Mlama, 2011).

In 2014, the FAO project "Communication for Development in Southern Africa" was a pioneer in supporting and enhancing development projects and programs through the use of participatory communication. The FAO project, placed under SADC, developed an innovative methodology known as Participatory Rural Communication Appraisal (PRCA), which combined participatory tools and techniques with a strong communication focus needed to enhance projects results and sustainability. FAO and SADC published a handbook on PRCA that was used in projects around the world.

The radio maintained a strong presence in research and practice into the 21st century. Radio was especially important in rural areas, as the work of the non-governmental organization Farm Radio International and its members across sub-Saharan Africa demonstrated. Knowledge exchange between development partners such as agricultural scientists and farmers were mediated through rural radio (Hambly, 2013).

Participatory development communication

The evolution of the participatory development communication school involved collaboration between First World and Third World development communication organizations. It focused on community involvement in development efforts and was influenced by Freirean critical pedagogy and the Los Baños school (Besette, 2014).

Development Communication or Communication for Development

The World Bank actively promotes this field through its Development Communication division and published the *Development Communication Sourcebook* in 2008, a resource addressing the history, concepts and practical applications of this discipline. World Bank tends to espouse and promote the title "Development Communication" while UNICEF uses "Communication for Development". The difference seems to be a matter of semantics and not ideology since the end goals of these global organizations are almost identical to each other. Communication for Development (C4D) goes beyond providing information. It involves understanding people, their beliefs and values, the social and cultural norms that shape their lives. It includes engaging communities and listening to adults and children as they identify problems, propose solutions and act upon them. Communication for development is seen as a two-way process for sharing ideas and knowledge using a range of communication tools and approaches that empower individuals and communities to take actions to improve their lives. World Bank defines Development Communication "as an interdisciplinary field, is based on empirical research that helps to build consensus while it facilitates the sharing of knowledge to achieve a positive change in the development initiative. It is not only about effective dissemination of information but also about using empirical research and two-way communications among stakeholders" (Development Communication division, the World Bank).

Examples of Development Communication across the Globe

One of the first examples of development communication was Farm Radio Forums in Canada. From 1941 to 1965 farmers met weekly to listen to radio programs, supplemented by printed materials and prepared questions to encourage discussion. At first, this was a response to the Great Depression and the need for increased food production in World War II. Later the Forums dealt with social and economic issues. This model of adult education or distance education was later adopted in India and Ghana (Besette, 2014). Radio DZLB was the community broadcasting station of UPLB College of Development Communication. It was a forerunner of the school-on-air (SOA) concept that provided informal education for farmers. DZLB hosted SOAs on nutrition, pest management and cooperatives.

DZLB aired educational programming for farmers and cooperatives. Established in 2009, Global South Development Magazine has been a recent example of development communication in practice. Instructional television was used in El Salvador during the 1970s to improve primary education. One problem was a lack of trained teachers. Teaching materials were improved to make them more relevant. More children attended school and graduation rates increased.

In the 1970s in Korea the Planned Parenthood Federation succeed in lowering birth rates and improving life in villages such as Oryu Li. It mainly used interpersonal communication in women's clubs. Oryu Li's success did not recur in all villages. The initial effort had the advantage of a remarkable local leader and visits from the provincial governor. A social marketing project in Bolivia in the 1980s tried to get women in the Cochabamba Valley to use soybeans in their cooking. This was an attempt to deal with chronic malnourishment among children. The project used cooking demonstrations, posters and broadcasts on local commercial radio stations. Some people tried soybeans but the outcome of the project was unclear.

In 1999 the US and DC Comics planned to distribute 600,000 comic books to children affected by the Kosovo War. The books were in Albanian and featured Superman and Wonder Woman. The aim was to teach children what to do when they find an unexploded land mine left over from Kosovo's civil war. The comic books instruct children not to touch and not to move, but instead to call an adult for help. Since 2002, Journalists for Human Rights, a Canadian NGO, has operated projects in Ghana, Sierra Leone, Liberia, and the Democratic Republic of the Congo. JHR works directly with journalists, providing monthly workshops, student sessions, on the job training and additional programs on a country by country basis.

Cuban Media and Education – In 1961, the year of education, the well known literacy campaign was initiated. Television and radio played a complementary role in the dissemination of literacy training programs. Live coverage of literacy worker and students was used to dramatise and this was reinforced on radio and in newspapers (Besette, 2014).

Social change

Social change involves alteration of the social order of a society. It may include changes in social institutions, social behaviours or social relations. Social change may refer to the notion of social progress or socio-cultural evolution, the philosophical idea that society moves forward by evolutionary means. It may refer to a paradigmatic change in the socio-economic structure, for instance the transition from feudalism to capitalism, or hypothetical future transition to some form of post-capitalism (Anderson, 2017).

Social Development

Social Development refers to how people develop social and emotional skills across the lifespan, with particular attention to childhood and adolescence. Healthy social development allows us to form positive relationships with family, friends, teachers, and other people in our lives.[1] Accordingly, it may also refer to social revolution, such as the Socialist revolution presented in Marxism, or to other social movements, such as Women's suffrage or the Civil rights movement. Social change may be driven through cultural, religious, economic, scientific or technological forces (Smith, 2014).

Types of changes

Social changes can vary according to speed and scope and impetus. Some research on the various types of social change focuses on social organizations such as corporations.

Different manifestations of change include:

- Fabian change - gradual and reformist incremental amelioration after the manner of the Fabian Society
- radical change[] - improvements root and branch in the style of political radicalism
- revolutionary change - abrupt, radical and drastic change, with implications of violence and of starting afresh (perhaps most popular as a political bogeyman)
- transformational change - a New-age version of radical change, and thus difficult to define
- continuous change, open-ended change - change (allegedly) for the sake of change
- top-down change - reliance on leadership
- bottom-up change - reliance on the huddled masses

MATERIALS AND METHODS

The methodological approach chosen for any piece of research is designed to provide proper data to answer the research questions and to attain the research objectives. The research is an exploratory type which investigates a phenomenon in which the researcher has little knowledge about. Exploratory research is usually undertaken when the research issue is badly understood. Cooper and Schindler (2003) argued that when the area of investigation is new or unclear, or if the research variables cannot be clearly defined, the researcher needs to follow an exploratory design in order to serve the purpose of the study and learn something new about the phenomenon. The study adopted a case study approach since it seemed more appropriate as this helps to understand complex issues through analysis of a number of events or conditions and their relationships. Case study is a strategy that explores in-depth a program, an event, a process or one or more individuals (Creswell, 2003).

RESULTS AND DISCUSSION

This section presents the analysis of findings and discussions base on the data collected from the field on the role communication plays in sustaining development projects. Analysis was run using SPSS version 25 and the following results were obtained.

Table 1: Communication influence in sustaining development projects.

SN	**Statement**	**N = 150 Mean (Std.)**	**Remark**
1	Communication is essential in sustaining development projects	2.53 (1.12)	Accepted
2	Communication has no influence in sustaining development projects	2.86 (1.20)	Accepted
3	Communication is partially important in terms of sustaining development projects	2.94 (1.25)	Rejected
	Total	**2.59**	Accepted

Source: Field survey, 2021. Mean magnitude: X ≥ 2.5 = Accepted, X ≤ 2.5 = Rejected

Results on Table 1 showed that communication has positive influence in sustaining development projects. The analysis indicates that respondents accepted on items 1 and 2, but rejected on item 3. The Grand mean 2.59 indicates that communication has positive influence in sustaining development projects.

In the context of this study a project is defined as an intervention that addresses a particular problem. Communication's influence on sustaining these projects is what the study set out to achieve. The development projects that have been implemented in the selected communities were investigated and it was realized that rural electrification and rural water supply were the major projects that have been implemented in the past few years. The study therefore concentrated on these two types of projects. The survey indicated that government and NGOs as well as development partners were involved in the provision of these projects.

Table 2: Importance of the use of communication in involving communities in development projects

SN	**Statement**	**N = 150 Mean (Std.)**	**Remark**
4	Communication important during implementation of projects	2.53 (1.12)	Accepted
5	Communication is important before implementation of projects	2.86 (1.20)	Accepted
6	Communication is important after implementation of projects	2.94 (1.25)	Accepted
	Total	**2.77**	Accepted

Source: Field survey, 2021. Mean magnitude: X ≥ 2.5 = Accepted, X ≤ 2.5 = Rejected

Results on Table 2 showed importance of the use of communication in involving communities in development projects. The analysis indicates that respondents accepted on items 4, 5 and 6. The Grand mean 2.77 indicates the importance of the use of communication in involving communities in development projects.

The study explored the use of communication before during and after the implementation of the projects under study. As indicated by FAO (2005), participatory communication approaches can bring together different stakeholders and groups into conversation with each other, and enable the poorest and most marginalized to have a powerful or influential voice in the decision and activities concerning their well-being. From the information gathered through interviews with respondents and focus group discussion, majority agreed that there was communication whilst a few people said there was absence of communication between implementers and communities before and during the implementation of the projects under study.

CONCLUSION AND RECOMMENDATIONS

The purpose of this paper was to explore the significance of development communication to social change. Qualitative research method, including document reviews, semi-structured interviews and a focus group were used to collect data. To identify the significance of development communication to social change the study first considered whether the three components of development communication thus social mobilization, advocacy and behaviour change communication were used to involve people before, during and after the implementation of projects. The study established that the components of development communication were used in the implementation of projects and involved members in the implementation of the project. Absence of participatory communication in some of the projects did not help implementers understand the challenges the community goes through in maintaining such developmental projects thus come together to find solutions to them. By facilitating mutual understanding and by building trust among stakeholders, communication becomes of critical value in fostering participation and social change.

Furthermore, the study revealed that participatory communication approaches can bring together different stakeholders and groups into conversation with each other, and enable the poorest and most marginalized to have a powerful or influential voice in the decision and activities concerning their well-being.

RECOMMENDATIONS

Based on the significance of development communication to social change, the study recommends as follows;

i. Firstly, project planners should design and adopt appropriate development communication model towards sustaining projects for project implementers and communities so as to get the desired social changes that come with such projects.
ii. Development communication should be all encompassing and should carry all along to as to achieve the desired social change that it comes with.
iii. Project implementers should adopt the social mobilization element of development communication by reaching out to opinion leaders who have the tendency to reach out to a large number of community members to inform them about the projects. This will help all members to become aware of the projects as these leaders have greater influence on the people.
iv. Development Communication should be used to raise awareness on the importance of members of communities playing their aspect of the social contract as this will enable the sustenance of social change that development communication brings.

ABSTRACT

The study reviewed the importance and use of ICTs in the dissemination of information for improving cashew production in Nigeria. The impact of ICTs in cashew production was extensively discussed, its benefits to weather and climate change, diseases and pest, market price as well as creation of new business opportunities were examined. Challenges facing the use of ICTs in cashew production was also looked into and finally recommendations were made that cashew farmers should be trained in the use of ICTs tools and soft loans to purchase ICTs equipment should be made available by government to cashew farmers.

Key words: ICTs use, Information dissemination, cashew production, cashew farmers, Nigeria

INTRODUCTION

Information has been identified as an important factor in improving agricultural production of any nation. It also serves as a very important tool for decision making. Human beings need information to be able to make informed decisions on any meaningful thing. Thus, for any development to take place especially in cashew production, relevant, efficient, and effective information need to be sought by cashew farmers. This therefore means that the agricultural sector needs timely and up-to-date information with the use of Information Communication Technologies (ICTs) (Ronke, 2005). There is hardly a field of human activity today that has not been touched by the use of ICTs. Information Communication Technologies comprise those mobiles devices and applications that help the processing, management, and exchange of information with a target audience. They include traditional telecommunications such as television, radio, video, cell phones and other smart devices and several modern technologies such as computers and the internet, sensors, Geographic Information Systems and satellites. Essentially, the purpose of ICT is to transfer information from one point to another. ICTs are essential to access digital information, whether online or offline. Their impact depend on which specific technology is used and also on farmers' level of literacy. Short message services (SMS), voice messages, short video trainings, audio messages, social media interventions and virtual extension platforms. All these can improve farmer-to-farmer and farmer to expert's information sharing. In many circumstances ICTs, like mobile phones, increase access to information by cashew famers in developing countries. Cashew farmers can achieve higher crop yields, as they get access to timely and better-quality information on their products and services as well as environmental and market conditions. ICTs promote learning, which can facilitate technology adoption among cashew farmers, but can also alert on early warning systems through better quality data and analysis. The use of ICTs has allowed the agriculture sector to surge ahead and change the way famers cultivate, harvest, and distribute agricultural commodities. The use of ICTs in agriculture quickens agricultural and rural development by adopting innovative ways to improve the existing information and communication processes. It has helped address several challenges associated with the traditional form of agriculture.

In fact, agriculture has changed as ICTs have become increasingly critical to farmers. Research showed that those farmers who have used ICTs in agriculture have increased their production. Similarly, those who have used the e-services, e-commerce applications also increased their income (Chapman and Slaymaker, 2002, Sideridis, 2010). The use of mobile phones by farmers in India led to reduction in price dispersion and also lead to perfect adherence to the law of one price (Jensen, 2007). In India, farmers obtain information about pesticides use and application as well as market details from internet (Meera *et al*., 2004). The study conducted in South Africa showed that mobile phones have given a positive impact on farmers' income (Aker and Mbiti, 2010).

Economic importance of Cashew (*Anacardium occidentale*) in Nigeria

Anacardium occidentale is a tree crop which originated from Brazil and it's an evergreen nut bearing tropical plants generally single-trunked of

12 cm. It is multipurpose tree crop with great economic importance to third world countries including Nigeria. The cashew tree has been cultivated for food and medicine for many years and its fruits are of economic value. This includes apple, nut, kernel and wood. Cashew apple is edible food rich in vitamin C. It can be dried, canned or eaten fresh from the tree. It can also be squeezed for fresh juice, which can then be fermented into cashew wine, cashew nut is consumed as roasted and salted nuts. In confectionery and bakery products, finely chopped kernels are used in the production of sweets, ice creams, cakes, and chocolates and as a paste to spread on bread (Akinwale, 2000). The kernels are well accepted in the United States of America and Western Europe because, of the high quality of the produce (Aliyu and Hammed, 2008). Cashew nut shell liquid is a dark liquid, which is extremely caustic. It is an important and versatile industrial raw material. It is used as raw material for phenolic resins and friction powder for the automotive industry. It is also used in molding of acid-resistant paints, polishes, enamels, and black lacquers which is used for decorating vessels. It can also be used in the production of insecticides and fungicides. In traditional medicine, it has been used in treating leprosy, elephantiasis, psoriasis, ringworm, warts, and corns (Akinwale, 2000). The cashew wood is also used for furniture and fishing boat (Adeigbe *et al*., 2015). Currently, large amount of cashew nuts produced in Nigeria are exported, as only very few companies are involved in local processing of the produce. The Cashew industry also provides jobs and employment for women and smallholder farmers and has a total annual trade worth N 24 billion, thus making the sector a major contributor to Nigeria's non-oil GDP (Akinwale, 2000). There are lots of challenges facing cashew production in Nigeria, these include diseases such as floral shoot die-back, twig die-back and root rot of cashew seedlings, climate change and marketability which ICTs assisted information dissemination could help to solve.

Benefits of using ICT in cashew Production in Nigeria

Internet has created a room for farmers to get latest information on market. Internet can increase many opportunities in cashew production. By using the internet, cashew farmers will get information about their production from different markets within and outside Nigeria. Similarly, it will help them to obtain information on new method to increase their goods and services. In addition to the internet is mobile phone. Mobile phone has reduced the gap among traders and farmers and same time farmers directly can communicate with buyers and customers to find the good price of their product. Mobile phones have created a new business opportunity for farmers and has given them access to information about market, health and weather condition. The mobile phones technologies can directly connect cashew farmers and buyers without any disturbances. Farmers have another advantage of mobile phones they do not need to go to market but directly communicate and ask the price of their production. In this context they save their money, time and energy (Muto, *et al*., 2011, Lee *et al*., 2013). Television can disseminate scientific and agricultural knowledge among cashew farmers with the discussion of agricultural experts. Cashew farmers can get information by watching the agriculture related programs on television (Murty and Albino, 2012). Radio was the more effective source of dissemination of agriculture information among famers (Abbas *et al*., 2009, Bolorunduro *et al*., 2004). Okwu *et al*. (2007). Radio provides information among rural farmers about marketing, weather, environmental, diseases, water management and pest monitoring to increase the productivity of agriculture in their country. Radio can broadcast new approaches, ideas, research findings and scientific information in cashew production.

Challenges associated with using ICT in Cashew Production in Nigeria

Singh *et al*. (2015) reported some existing issues of ICT use in agriculture to include inadequate accessibility of ICT services to rural farmers, lack of basic skills of using ICT facilities in agriculture, inability of government to deliver adequate ICT knowledge to farmers. Access to the internet and telecommunications are mostly limited to urban areas in many developing countries while the rural areas remain untouched with new technology (Kale *et al*., 2015). Inadequate, and unstable power supply, cost of hardware and software are very high (Kale *et al*., 2015; Wyche and Steinfield, 2015). Unreliability and poor connectivity of the internet, and regular barriers to power distributions could be a major constraint to ICTs usage among cashew farmers in Nigeria. In view of the foregoing, it is clearly understood that inadequate basic ICT skills posed a serious challenge towards reaping the impact of ICT for agricultural growth.

CONCLUSION AND RECOMMENDATIONS

From the foregoing, we can see that cashew is a valuable economic tree. The crop provides food,

ISSN: 2814-0508

income and also a source of livelihood that create job opportunities for relevant stakeholders. Despite all these benefits, there are lots of challenges facing cashew farmers along value chain in Nigeria. These challenges can be managed if cashew farmers can get accurate and up to date information through the use of ICTs. It is therefore recommended that:

1. Cashew farmers should develop interest in the use of ICTs and should be trained by IT expert in the use of sophisticated ICTs tools.

2. Government should assist them with soft loans to purchase some of these ICTs equipment.

ABSTRACT

The attenuation of millimeter waves radio signal by rain and its implication on the dissemination of agricultural research in Nigeria was investigated. The data was collected from the Tropospheric Data Acquisition network (TRODAN), the International Institute for Tropical Agriculture (IITA), Bowen University Iwo and the Federal University of Technology, Akure. The rainfall rates were measured at 5 and 1-minutes integration time and the Lavergnat and Gole model was used for the conversion of the measured 5 minute to equivalent 1-minute values. The International Telecommunications Union (ITU) - Radio sector (R) 530-17 recommendation was used obtain the specific and path attenuation. The results revealed that as the percentage of time deceases from 1 to 0.0001%, the rainfall rate increases and vice versa. The specific attenuation frequency threshold at the 0.01% exceedance was 120 and 150GHz and it ranged from 11.81 to 35.05dB/km and 20.54 to 35.63dB/km respectively. The clear signal band path attenuation frequency threshold at 20km path length was 40 and 45GHz and it ranged from 168.23dB to 92.11dB. These results suggest the inclusion of the estimated attenuation values by radio propagation engineers in communication equipment designs for Nigeria.

Key words: Rainfall rate, millimeter wave, rain induced attenuation, radio signal, agricultural research

INTRODUCTION

Millimeter wave is the highest radio frequency band in practical use. It is the next band above microwave and lies between 30-300 GHz of the electromagnetic spectrum. It is characterized by narrow beamwidth, wide bandwidth spectrum and high frequency re-use potential (Chittimoju and Yalavarthi, 2021). Millimeter wave is the ideal candidate for certain applications such as provision of higher data rates in supporting applications such as Internet calls (Voice-Over-IP), local network remote access, inter- active audio-visual conferencing, wireless internet access of high speed, multimedia information broadcasting and file transfer (Karipidis, 2021).

At the millimetre wave frequency bands, attenuation by rain is considered the most crucial limiting factors that impairs the performance of fixed terrestrial wireless systems (Abayomi *et al*., 2019). Communication links reliability, availability and performance is adversely affected by the absorption and scattering of radio signals by rain which causes a decrease in the amplitude of the propagated signal (Shrestha *et al*., 2019) and leads to cross talk. Though a methodological approach has been developed by the International Telecommunications Union (ITU) - Radio sector which is useful for radio signal attenuation prediction due to rain on any terrestrial paths, however, in the tropical climate, the model does not perform well because of its dependence on temperate climates based data (Melloda *et al*., 2007). With the increase in spectrum occupancy of the volumes of agricultural research information in Nigeria and higher bandwidth demand to accommodate them, the need to explore the attenuating effect of rain on the carrier technology has become imperative.

MATERIALS AND METHODS

The data used for this study was sourced from the Tropospheric Data Acquisition Network (TRODAN), a project put forward by the Nigerian Centre for Atmospheric Research (CAR); the International Institute for Tropical Agriculture (IITA), Federal University of Agriculture, Akure and Bowen University, Iwo. The equipment used was with rain gauge of 5 minutes' resolution. The accuracy is up to 1 inch/hr: ±1% while the operating temperature is from 0° to +50°C.The study area covers all the agro-ecological zones of Nigeria with the exception of the sahel savanna and the duration of the study was averaged to five years. Table 1 shows the features of the study sites. The Lavergnat and Gole Model (equation 1) was used for the 5 to 1-minute integration time conversion; the specific attenuation, Y_R (dB/km) also referred to as attenuation per unit distance was determined with equation (2). The path attenuation, $A_{0.01}$ (dB) at 0.01% exceedance, the equivalence of 99.99% radio signal availability, was obtained at the maximum recommended path length of 60km by ITU-R (ITU-R 530-17, 2017) and 20 km for millimeter wave radio equipment deployment as shown in equation 2.

$$Q_c\left(r, t\right) = K^{\xi-1} Q_c\left(rk^{\xi-1}, kt\right) \quad (1)$$

Where $Q_c(r,t)$ is the cumulative probability function of rain rate r that would be obtained with a rain gauge having an integration time t.

$$\gamma_R = kR^{\alpha} \quad (2)$$

k and α = functions of frequency (GHz) ranging from 1GHz to 1000 GHz and R is the rainfall rate in mm/hr

$$A_{0.01} = \gamma_R d_{eff} = \gamma_R dr \; dB \quad (3)$$

where d_{eff} is the effective path length.

RESULTS AND DISCUSSION

Annual rainfall rates cumulative distribution

The variation of the yearly cumulative distribution of the averaged 1-minute integration time rainfall rate over the agro-ecological zones are shown in Figure 1(a - f). It can be observed from the figure that as percentage of time of rainfall rate exceedance decreases from 1 to 0.0001%, the rainfall rate increases and vice versa. In effect, the higher the rainfall rate, the higher the annual failure rate of millimeter wave radio equipment.

Rainfall attenuation of signal per unit distance

The specific attenuation was calculated for both for the horizontal and vertical polarization of the millimeter radio waves by rain. As shown in Table 2, the specific rain attenuation threshold across the zones was 120 GHz or 150 GHz. As observed, there is a slight difference between the specific attenuation at the horizontal polarisation and the vertical polarisation. In the Derived Savanna zone, the maximum specific attenuation predicted by ITU-R was 30.56 dB/km which differed from attenuation of 29.78 dB/km derived from measured rainfall by 0.78 dB/km. On the other hand, at the Humid Forest zone, the maximum predicted value of specific attenuation by ITU-R was 33.52 dB/km and it differed from the attenuation of 35.91 dB/km derived from measured rainfall by about 2.30 dB/km. Other zones follow the same trend, however with variation in the differences in specific attenuation due to rain.

Estimating path attenuation of millimeter radio wave

The path attenuation across all the zones was plotted at their frequency threshold of 120 GHz and 150 GHz respectively and the maximum recommended path length of 60km by ITU-R and 20 km for millimeter radio equipment deployment. As deduced from in Figures 2, the maximum frequency for clear signals transmission at 120 and 150GHz frequency threshold is 40 and 45 GHz and respectively. The clear signal band path attenuation frequency threshold at 20km path length ranged from 168.23dB to 92.11dB. The transmitted signal suffers from overlap beyond these frequency bands.

CONCLUSION

Rainfall constitutes a major impairment on the dissemination of agricultural research information through the use of millimeter wave radio technology; it impairs the effective utilization of the available huge bandwidth. There is an inverse relationship between the percentage exceedance and the rainfall rate across the agro-ecological zones. The specific attenuation threshold is 120 and 150GHz while the clear signal band frequency threshold is 40 and 45GHz. Hence for effective dissemination of agricultural research information in Nigeria during rainfall, the clear signal band frequency threshold should be used for the design of communication equipment for Nigeria inorder to forestall failures.

Table 1. Features of the study sites

Sites	Coordinates	Altitude	Average Annual rainfall (mm/yr)	Agro-ecological zone
Jos	9.93 °N, 8.89°E	1280	812.40	Mid altitude savanna

ABSTRACT

Knowledge of high-quality seedling production is a significant way to assist tree crop farmers achieve improved profitability in their enterprise. This is because quality seedlings as well as variety selection set the maximum performance level for tree crop plants. Being key players in the seedling production industry, this study examines the perception and information needs of smallholder horticulturists on cashew seedlings value addition in Kwara State, Nigeria. A two-stage sampling technique was used in selecting twenty-three horticulturists across the state. Structured interview schedule was used in collecting data which was analyzed using frequency counts, percentages, means and chi-square analysis. The results show that 73.9% of the respondents were between the ages of 41 and 50, mostly males (91.3%) and were married (95.7%). All the respondents had formal education with average years of experience in horticulture as 21.2 years. They had positive perception towards cashew seedlings value addition initiative (WMS =3.25) and high information needs on the initiative (WMS =1.86). It was recommended that tailor made advisory services should be packaged by extension organizations and other stakeholders for horticulturists in the areas of information needs indicated so as to enhance their use of the initiatives in seedling production. Also, youths should be educated to appreciate horticulture enterprise as a viable job option.

Key words: cashew, seedlings, plant nurseries, orchards, value addition

INTRODUCTION

In Nigeria, horticulturist are important service providers in tree plant seed sub-sector. The actors in the horticultural businesses are responsible for seedling inputs in tree crop production. Most nursery operations are carried out by horticulturist. Seedling production enterprise contributes to income generation and socio-economic development of a country (Eko et. al., 2021). Successful plant production is dependent on the viability of the available planting materials. Viable seedlings are achieved through good nursery management techniques and skills of the operators. Plants that are poorly managed in the nursery usually struggle to perform well once planted out in the field. In order to enhance the performance of planting materials, adding value that can improve their viability is important to maximize the potentials of the seedling sub-sector. Characteristics such as trueness to variety, survival rate, purity, vigor, and appearance are important feature attainable through value addition during seedling production. To achieve great yield potentials, farmers must use high-quality, healthy and vigorous seedlings. Seeds and seedlings are noted as the foundation of agriculture especially as it relates to crop production. Hence, for sustainable crop production, seeds and seedling production have been receiving prime attention in agricultural research and technology development. For instance, research efforts have provided technologies in improved seed varieties, use of biodegradable packs, standardized operational procedures etc. These technologies have modernized most farming's day-to-day operations.

In tree crop plant expansion, cashew is receiving special attention because of its current demand globally. In Nigeria, cashew industry is becoming a major contributor to the nation's non-oil GDP. Nigeria exported cashew nuts (both in-shell and shelled) valued at N13.71 billion in the first quarter of 2021 (National Bureau of Statistics, 2021). The industry is also a vibrant employer, providing about 600,000 jobs. Cashew farming is quite popular with a total land area of 320,00 hectares being used for the cultivation of the crop. Cashew is cultivated in more than 27 states in Nigeria and has high potential to increase production beyond any of the competitors like cocoa and palm. Despite these great potentials, cashew industry maybe unable to attain its full potential if quality planting materials are not available to the farmers. Therefore, nursery operators have vital role to play in the provision of viable and quality cashew seeds and seedlings. To meet this task, access to requisite information on proper handling of seedlings and value addition is a sure way to guarantee good planting material distribution in the subsector. In order to articulate training programmes that can improve the knowledge of actors in the nursery businesses, it is important to investigate their information needs for curriculum development. It was against this background that this present study was carried out to examine the perception and information needs of smallholder horticulturists on cashew seedlings value addition in Kwara State, Nigeria. To establish this aim, the following objectives were considered;

1. determine the socioeconomic characteristics of the smallholder horticulturists;
2. examine their perception of cashew seedlings value addition and
3. identify the information needs on cashew seedlings value addition.

MATERIALS AND METHODS

The study was carried out in Kwara State, Nigeria. Kwara State covers eight percent of the total land area of Nigeria; that is, an area of 74,256 km^2. The state has a tropical climate, with a total population of 3,192,893 (National Bureau of Statistics, 2018) and a density of 66 people km^{-2}. The state is typically agrarian. Eighty percent of the population reside in rural areas and 90% of the population are farmers (Yusuf *et al*., 2016). The climate, vegetation pattern and soil make the state suitable for cultivation of a wide variety of tree crops of which cashew takes the lead. The state has 16 Local Government Areas (LGAs). The Agricultural Development project (ADP) classified the 16 LGAs into 4 agricultural zones, 23 blocks and 184 cells in consonance with ecological characteristics and cultural practices. The population for the study comprises all horticulturist in Kwara State. A two-stage sampling technique was used to select twenty-three smallholder horticulturists across the state. The first stage involved the purposive selection of six local government area in the state based on the availability of horticultural businesses in the areas. The second stage was an aided-selection of twenty-three horticulturists in the selected LGAs. Snowballing approach was used to locate the them. This selection approach was used because there are no organized horticulture systems in the state. Structured interview schedule was used to collect data for the study. Data were summarized and presented using frequency counts, percentages, mean and standard deviations. The socioeconomic profile of the horticulturists including sex, marital status and educational attainment were measured in a nominal scale. Data on age, years of experience in nursery operations/horticultural enterprise and household size were measured on an interval scale. perception on cashew seedlings value addition was measured using five-point likert scale of 5= Strongly agreed, 4= Agreed, 3= Undecided, 2= Disagreed and 1= Strongly disagreed. The frequency values on the Likert scale were added to obtain 15 and a mean score of 3; hence variables with mean scores of 3 or above were regarded as positive perception while mean scores below 3 were considered as negative. The information needs on cashew seedlings value addition initiative was measured using four-point likert-type scale of 2= Highly needed, 1= Needed and 0=Not needed.

RESULTS AND DISCUSSION

Socioeconomic Characteristics of the Respondents

Data in Table 1 reveals that a notable proportion of the respondents (73.9%) falls between the age bracket of 41-50 years. This age group, since they are relatively young have the tendency of positively responding to innovations that could enhance their business. Majority (91.3%) of the respondents were males. Horticultural enterprise like other farming businesses is labour intensive, especially the nursery plant management routines, making men play leading roles in the horticultural industry. A major proportion (95.7%) of the respondents are married. Being married gives a sense of responsibility that makes individuals seek information to improve their business performance (Olabanji and Fabiyi, 2021). All the respondents are educated at secondary and tertiary levels. Estruk and Oren (2014) mentioned that education enables easier access to information from various sources and facilitates knowledge generation out of those sources. More than two-third (78.3%) of the respondents have 6-10 household size with an average of 7 persons. Household size has been linked to the availability of 'own' labour that could be of assistance in the developing the enterprise. Averagely, the respondents hold 21.2 years of experience in horticultural ventures and majority (78.3%) have not received extension contacts in the last 2 years. This is below the Food and Agricultural Organization (FAO) recommendation that farmers are expected to be visited at least once in every two weeks, or a minimum of 15 extension contacts in a farming season (Idrisa and Ogunbameru, 2012).

Table 1: Distribution of respondents based on socioeconomic characteristics

Socioeconomic Variables	Frequencies	Percentages	Mean
Age of Respondents			
Less than 30	01	4.4	
31-40	04	17.3	44.2 years
41-50	17	73.9	
Above 51	01	4.4	
Sex			
Male	21	91.3	
Female	02	10.0	
Marital Status			
Single	01	0.0	
Married	22	95.7	
Educational Status			
Secondary	04	17.3	
Tertiary	19	82.6	
Household Size			
1-5	05	21.7	7 persons
6-10	18	78.3	
Years of experience			
Less than 10	01	4.4	
11-20	03	13.0	
21-30	17	73.9	21.2 years
31 and above	02	8.7	
Contact with extension workers in the last 2 years			
Yes	05	21.7	
No	18	78.3	

Perception of cashew seedlings value addition initiative

Data on Table 2 shows that the respondents have positive perception towards cashew seedlings value addition initiative (WMS =3.25). Positive perception is a pointer to acceptance of an innovation and this could impact adoption positively. The Table also shows that the standard deviations were all less than 1.0 indicating that the respondents' individual scores as regards their perception on the cashew seedling value addition initiative are more closely related.

Table 2: Distribution of the respondents according to their perception of cashew seedling value addition initiative

Perception Statements	WMS	Std. Dev	Decisions
Too much investments will be required to implement the value addition initiative	2.72	0.680	Negative
Adding values to my seedlings can give me hedge over competitors	3.01	0.731	Positive
In order to sustain my income in cashew seedling production, value addition will be helpful.	4.45	0.543	Positive
Activities other than the normal routine will be stressful	3.12	0.812	Positive
Additional cost of production may not be appreciated by buyers	3.17	0.634	Positive
Asides the normal practices, I want to do other things to increase the pleasure in my work.	3.16	0.411	Positive
A lot of awareness will be needed to make customers see difference in value added seedlings and the normal one	2.85	0.833	Negative
I believe that I can increase the margins of my production through the initiative.	3.11	0.759	Positive
Adding value seedling will show unique trait that will enhance patronage from buyers	3.68	0.556	Positive
The initiative can improve cashew seedling production across board	3.21	0.785	Positive
Cumulative average	3.25	0.674	POSITIVE

Information Needs on Cashew Seedlings Value Addition

Data on Table 3 shows that the respondents require high information needs on various aspects of the initiative (WMS =1.86). Wilson (2000) perceives information seeking behaviour as the purposive seeking for information as a consequence of need to satisfy some goals.

Table 3: Distribution of the respondents according to their information needs

Information Needs	Extremely Needed	Highly Needed	Moderately Needed	Not Needed	WMS	Decision
Systemic treatments of developing seedling	5 (21.7)	9 (39.1)	07 (30.5)	2 (8.7)	1.74	Required
Improvement of seedlings material attributes (e.g., dormancy status, water relations and morphology)	10 (43.5)	7 (30.4)	5 (21.7)	1 (4.3)	2.13	Required
Improvement of seedlings performance attributes (e.g., root growth potential, hardiness to frost, and resistance to stress)	7 (30.5)	6 (26.1)	5 (21.7)	5 (21.7)	1.65	Required
Grafting of good performing seedlings	14 (60.9)	5 (21.7)	3 (13.1)	1 (4.3)	2.39	Required
Genetic traits considerations	5 (21.7)	6 (26.1)	5 (21.7)	7 (30.5)	1.39	Not Needed
Sourcing for foundation seed (registered) for seedlings production	5 (21.7)	5 (21.7)	6 (26.1)	7 (30.5)	1.35	Not Needed
Proper nutrient management	7 (30.5)	7 (30.5)	4 (17.3)	5 (21.7)	1.70	Required
Treatment of seeds before sowing	6 (26.1)	8 (34.8)	6 (26.1)	3 (13.0)	1.74	Required
Application of improved nutrient solutions	8 (34.8)	7 (30.5)	6 (26.1)	2 (8.7)	1.91	Required
Sourcing for biodegradable packs	16 (69.6)	5 (21.7)	2 (8.7)	0 (0.0)	2.61	Required
Cumulative average					1.86	Required

CONCLUSION AND RECOMMENDATIONS

The study concludes that the positive perception of the respondents on the initiative is a good pointer that adoption of improved practices is possible in the area. However, poor extension contacts with horticulturists could be a setback in meeting their information needs. It was therefore recommended that more extension service should be provided to the horticulturist, tailor made advisory services should be packaged by extension organizations and other stakeholders in the areas of information needs indicated. Also, people should be enlightened on the profitability potential of value addition on seedlings as an enterprise. This could encourage youths to go into the business thereby sustaining livelihood at the same time reducing unemployment.

INFORMATION SOURCING BY VEGETABLE FARMERS IN OKIGWE LOCAL GOVERNMENT AREA, IMO STATE NIGERIA

Uwazuruike, S.C.

Department of Information and Documentation, National Horticultural Research Institute, P.M.B 1076, Mbato Out-Station, Okigwe, Imo State, Nigeria

Corresponding author's e-mail: stellauwazurike@gmail.com

ABSTRACT

Information is key to enhanced productivity in any life endeavour. In vegetable production availability of the required information could make a difference in the outcome of the production activity. Information sourcing by vegetable farmers in Okigwe Local Government of Imo State has scarcely been documented hence this study. The research, therefore, assessed information seeking by vegetable farmers in the Local Government Area. A structured questionnaire was designed and used to elicit responses for vegetable farmers in 20 out of the 22 autonomous communities of the Local government area. Two (2) difficult to access autonomous communities were left out. Five farmers were purposely chosen from each community and the questionnaire administered to them totaling 100 questionnaires only were filled, returned and analyzed. The result shows that there are more female (54%) than male farmers (41%) of all the farmers were aged between 20 and 49 years (59%) were married and 60% had more than primary school education. The farmers grew various vegetables but telfairia (ugu) and okro topped the list and the farmers were small-holders with plots less than I hectare of land. The highest sources of information to the farmers were from colleagues (36%) and NIHORT (31%). Information sourcing was more at the beginning of the farming season (47%) and when a problem arises (42%) and they sourced information more on vegetable seed (43%) and fertilizer use (34%). Lack of funds (41%) and insecurity (39%) constituted the major constraints to the farmers. It is recommended that agricultural extension services be intensified by the government extension agents in the communities and NIHORT as a research institute should establish out- reaches to the communities.

Key words: Information sourcing, vegetable farmers, Okigwe L.G.A.

INTRODUCTION

Information is key to any productive activity as one cannot successfully act beyond the level of information at his disposal in agriculture, access to adequate information is very necessary to increase output (Mgbada, 2006). Availability of sufficient information to farmers helps them bridge the gap occasioned by their lack of knowledge in various aspects of agricultural production. Fagbola (2015) asserts that relevant knowledge can aid farmers in the high production of horticultural crops. Also, Oladele (2011) concurs that lack of agricultural knowledge and information is a key factor that has greatly limited agricultural advancement in developing countries. Oladunjoye et al. (2015) reported that improper utilization of research information in agriculture has been one of the causes of low crop yield in Sub-Saharan Africa. In Nigeria specifically, Aina, Kaniki and Ojiambo (1995) identified low utilization of research information as one of the major problems affecting agricultural transformation in Nigeria. Thus, Taiwo Oyaniran (2020) reported that lack of financing for small-scale farmers and inefficient transport system affects vegetable farmers in remote areas.

The increasing yield of vegetables is very important because of the role vegetables play in the health and wealth of humans. Vegetables are natural sources of vitamins, minerals and sometimes fats and oils Ezeibe (2011). Ugwuoke et al (2015) reported that vegetables supply essential micronutrients in human nutrition that act as preventive agents to several ailments. Vegetables are produced and consumed in large quantities, especially in Southern Nigeria. Ugwuoke et al. (2015) According to Enete and Okon (2010) vegetable production (Fluted pumpkin) has become a major occupation of many small scale producers in both rural and semi-urban communities in Abia state. An increase in vegetable production may improve food security and offer employment opportunities to the populace, especially women who form a substantial production community. (Mlozi, 2003).

The potentials of vegetable production for wealth creation has been documented by Ugwuoke et al. (2015) who reported that vegetable production offers a significant opportunity for poor women to earn a living as producers and marketers. F.A.O. (2006) also noted that there has been a rise in production of vegetables in general induced by growing public demand driven by the enhanced consumer of the dietary and health benefits of fresh vegetable consumption for instance, Hart et al. (2005) noted that in Nigeria, vegetable consumption of rage of 59-130 person/day is far below the recommended average for healthy living. It is, therefore, imperative to increase the production of vegetables in Okigwe L.G.A to create and improve the health of the inhabitants of the area. One of the ways of improving production is by sourcing information from the appropriate sources. This study investigates the sourcing of information by vegetable farmers in the Okigwe Local Government Area of Imo State, Nigeria.

MATERIALS AND METHODS

The study was carried out in the Okigwe Local Government Area of Imo state. Okigwe lies between latitudes 5^0 30' North to 5^0 57' North and longitudes 7^0 40'E to 7^0 5S' East with and has a population of 132,237. The Local government area consists of twenty-two autonomous communities. With the assistance of the ADP agents in those autonomous communities, 5 questionnaires were purposively distributed to prominent vegetable farmers is identified by the agent. Questionnaires were not distributed to two far-thing autonomous communities because of their accessibility. Thus a total of 100 questionnaires were distributed and the return rate was 95 percent as five of the questionnaires were not returned. The structured questionnaire sought information on the demographic characteristics of the respondents, types of vegetables grown, farm size, where they source information, when information is sourced, types of information sourced etc. The results were analyzed and presented in frequency counts and percentages.

RESULTS AND DISCUSSION

A total of 100 research questionnaires were distributed and 95 were filled and returned giving a percentage of 95%. The Socio-economic characteristics of Respondents are presented in tables 1,2,3 below.

The result shows that there were more female (approximately 57%) vegetable farmers than male ones (approximately 43%). This is understandable because vegetable crops are regarded as belonging to women while such crops like yam are the preserves of men.

Table 1: Gender of respondents

Gender	Frequency	Percentage of respondent
M	41	43.16
F	54	56.84
	95	100.00

Table 2 shows that majority of the vegetable farmers in the L.G.A fall between 20-59 years of age. This age range could be considered energetic and productive. However, further analysis shows that some (approximately 16%) of the respondents face between the age brasher of 20-25 years of age. This age is when some young people, through full of energy but are lethargic to physical agricultural production preferring to migrate to cities to look for white-collar (jobs or any jobs at all).

Table 2: Ages of Respondents

Age Range	No Respondents	Percentage of Respondent
20-29	15	15.79
30-39	19	20.00
40-49	34	35.79
50-59	21	22.11
60 <	6	6.32
		100

The result presented in Table 3 shows that almost 59% of the respondents are married, another 24.21% widowed, while 7.37% are divorced and about 10% (9) are still single. This implies that vegetable production is not discriminatory to marital status. And this could be as a result that it offers the producers returns that encourage all to participate. However, the distribution of respondents shows that married people contributed almost two-thirds (58.95%) of the respondents followed by widows and widowers, (about a quarter of the respondents while the singles and divorced make up the rest.

Table 3: Marital Status of Respondents

Marital Status	No of Respondents	Percentage of Respondents
Married	56	58.95
Widowed	23	24.21
Divorced	7	7.37
Single	9	9.47
	95	100

Source: Field Survey, 2021.

Table 4 describes the distribution of the educational qualification of the respondents. The result shows that 38(40%) of the respondents had only the First School Leaving Certificate. Another 26.32% had the Secondary School Certificate. A combined percentage of 28.42% of N.D/ NCE, HND and B.Sc was found to be growing vegetables in Okigwe L.G.A. It was also revealed that about 5% of the respondents had no formal education.

The result shows that since some of the respondents had no formal education (45%) have low education, information seeking by them may be deterred. However, as the result indicates that more than half of the respondents are literate, they would seek or source information that will improve their vegetable production techniques. This may also diffuse into the communities. In all, the correspondents are both youthful and educated and most likely seek for information to assist them in their endeavours.

Table 4: Educational Qualification of Respondents

Educational Qualification	Number of Respondents	Percentage of Respondents
FSLC	38	40.00
WAEC/GCE	25	26.32
National Diploma/ Nigeria Certificate of Education	14	14.74
HND/BSC	13	13.68
None of the above	95	5.26
Total	95	100

Source: Field Survey, 2021

Table 5 shows that most respondents grew more than one vegetable but the more common vegetables grown were okra by almost two-thirds of the respondents and Ugu, by more than two-thirds of the respondents and a combination of other vegetables by others. It is obvious from the results that a respondent grows both okra, ugu, Amaranthus, pepper and melon, though it should be noted that these two vegetables (Okra and ugu) are compliments. This result agrees with Enete and Okon (2010) who confirmed that fluted pumpkin (ugu) has become a major occupation of many small scale producers in both rural and semi-urban communities in Abia State.

Table 5: Types of vegetables grown by Respondents

Types of vegetable Grown	No. of Respondents	% of Respondents
Okra	56	58.90
Fluted pumpkin (ugu)	60	63.16
Pepper	21	22.11
Tomatoes	20	21.05
Melon	25	26.32
Green (Amaranthus)	22	23.16
Garden Egg	15	15.79
Other Vegetables	4	4.21
Total	223*	224.60*

*There were multiple responses. Source: Field Survey, 2021.

The study showed that farm size among the respondent ranged from small plots of 1-5 plots of land (35.79) to bigger farmers who owned 1-acre farms (27.37%) and farmers who owned about a hectare of the vegetable farm (27.37). Respondents in this survey fall into the small-holders, category with the characteristic of small farm size (Table 6).

ISSN: 2814-0508

Table 6: Farm size of the respondent

Farm size	No. of Respondents	% of Respondents
1 hectare	35	36.84
1 acre	24	25.26
1-5 plots of land	34	35.79
6 – 10 plots of land	2	2.11
Total	95	100

Source: Field Survey, 2021.

Table 7 shows the sources of information by respondents. As expected, there were multiple responses as vegetable producers in the Okigwe Local Government Area sourced their information from more than one source. NIHORT was the highest (30.53%) Institutional source of information. Another institutional source of information was from the ADP (15.79) is (through the agents in the community) and 12.63% sought their information from the farmers' co-operative society. The university as a source of information was the least used by the respondent; this could be as a result of no University around Okigwe where they could go. The Abia State University in nearby Uturu has its Agriculture Faculty in Umuahia, which entails a cost to travel to. Workshops and Seminars was another source of information for the vegetable farmers in Okigwe L.G.A. as about 15% of respondents said they get their information from that source. Social Media (4.21%) and Radio/TV Programmes (8.42%) also contribute as sources of information to the surveyed vegetable farmers.

However, the highest source of information for the vegetable farmers in Okigwe L.G.A. area of Imo State is from personal contact with their colleagues. This practice is forth with possible misinformation as (35.79%) they can only give as much as they have. The remedy to this is to ensure that adequate and correct information is made available to the farmers.

Table 7: Where Respondent seek information from

From where do Respondents Seek Information	No. of Respondents	% of Respondents
Agricultural Development Programme (ADP)	15	15.79
University	2	2.11
NIHORT	29	30.53
Farmers Co-operative Society	12	12.63
Workshops/Seminars	14	14.74
Personal Contracts with Colleagues	34	35.79
Social Media (Agric. Platform)	4	4.21
Radio/TV Programme	8	8.42
Total	**118***	**124.24***

*There were multiple responses. Source: Field Survey, 2021.

Time of Seeking Information

The time of seeking information by the respondents is presented in Table 8. The farmers (47.36) seek information most at the beginning of the farming season while another good proportion (42.10%) are reactionary and therefore firefights, only seeking information when a problem exists. A percentage of respondents (10.53%) just seek information perfunctorily.

Since the need to gather information is to help improve production, farmers should be encouraged to being to source information easily as this source would prepare them better for the farming season.

Table 8: When respondents seek information

When do you seek Information	No. of Respondents	Percentage
Before the beginning of the farming season	45	47.36
In the middle of the farming season	10	10.53
When there is a problem at the farm	40	42.10
Total	95	400

Source: Field Survey, 2021.

Table 9 reveals that a high percentage of the farmers (43.17%) seek information on vegetable seed, another 34.34% of the respondents seek information on fertilizer, including types, sources, application, and price. Vegetable growers in the area offer to have become accustomed to the varieties they have as less than one-fifth (16.67%) seek information on vegetable varieties. However, the result of the survey shows that the agronomy of the vegetables and marketing them are the least areas where the respondents seek information. This suggests that any information being passed to the farmers should major on seeds, availability, costs, and general information on vegetable seeds. Another information the farmers may consider important would be fertilizer.

Table 9: Type of information sought by vegetable farmers

Type of Information Sought Respondents	Number of Respondents	Percentage
Information Vegetable varieties	17	16.67
Information of vegetable seeds	44	43.14
Information on fertilizer use	35	34.34
Information Marketing	3	3.16
Information on Agronomy	3	3.16
Total	**102***	**100**

*Multiple Responses. Source: Field Survey, 2021.

Constraints to information seeking by the Okigwe Vegetable Farmers

The result shown in Table 10 indicates that vegetable growers in Okigwe L.G.A of Imo State encounter various challenges in sourcing information. The greatest constraint faced by the vegetable growers is lack of adequate finance, this could be to travel to sources of information. Another constraint faced by the vegetable grows is security. Security of lives in some parts of the country has been a challenge and farmers out of fear do not move around these days as much as in the past few years.

Vegetable farmers in the L.G.A. also are challenged by accessibility to sources of information perhaps as a result of poor roads. Improved infrastructure and government taking the required information closer to the farmers would be great assistance to them. Least of the challenges faced by the vegetable producer's non-existent power supply particularly for those who source information from the radio and television sets.

Table 10: Challenges (Constraints) to information seeking by Respondents.

Challenges (Constraint)	No. of Respondents	Percentage
Inadequate fund	39	41.01
Insecurity	37	39.00
Accessibility to sources of information	12	12.63
Power Supply	7	7.36
Total	95	100.00

SUMMARY

This study investigates information-sourcing among vegetable growers in Okigwe Local Government Area of Imo State of Nigeria.

The demographic characteristics of the farmers were captured by the research instrument. The result shows that the vegetable growers are more of females (54%), aged between 20 and 59 years of age, more of married people (59%).However, about a quarter of the respondents are widowed and less than 20% are either divorced or single. Most of the vegetable producers are educated to varying levels. The table shows that 40% but are only Primary School Leavers, 26% are Secondary School Leavers, about 15% are with the National Diploma or NCE. It is interesting to note that about 14% of the respondents are graduates, driven to vegetable production perhaps by joblessness.

The results also showed that the respondents grew an assortment of vegetables but Telfairia (Ugu) and okra, are the two major ones grown by the respondents. The farmers are mainly small-holders, with farm size ranging from few plots of land to 1 hectare of land as the largest farm size. The vegetable growers in Okigwe L.G.A. as seen from the results sourced their information through personal contact with Colleagues, from NIHORT Sub-station in the L.G.A, A.D.P, and Workshops in that order. The result shows that close to 50% of the surveyed vegetable farmers begin seeking the information at the beginning of the farming season. Another 42% start seeking information when there is a problem at the farm. The major information they seek is on vegetable seeds and fertilizer use, though some (about 17%) vegetable growers also seek information regarding better yielding vegetable varieties. The major constraints faced by the farmers are inadequate funds, insecurity in sourcing information. Accessibility to sources of information and power supply are also constraints but to a lesser degree.

CONCLUSION

Adequate information of the right time is crucial to improving the productivity of vegetable growers.

The availability of the right information at the right time. This study has shown that the vegetable growers source information more from their co-producers, and the closest research institute (NIHORT). The study also revealed that they start seeking information both at the beginning of the season and when a problem arises. However, they are constrained by a lack of funds to source the desired information and the information sought by these producers is more on vegetable seeds and varieties.

RECOMMENDATIONS

Based on the results of the study, the researcher makes the following recommendations

(1) In view of the challenges to accessing the desired information on seeds, the research institute should establish closer links with the vegetable growers in the different communities.

(2) The government should make extension services with the right information, should be made more available to the vegetable growers in the Okigwe Local Government.

(3) Agricultural loan facilities should also be made available to these small scale vegetable farmers.

ABSTRACT

Coffee is an important cash crop and has contributed greatly to gross domestic product of Nigeria economy. The study was conducted to assess the information sources to coffee farmers on coffee production technologies utilization in Kogi State. More specifically, it examined the socioeconomic characteristics of the farmers, identified various sources of information by coffee farmers on coffee production technologies utilization and determine levels of coffee production technologies utilization among coffee farmers. A set of pre- tested questionnaire was used to gather information from 100 farmers that were selected through multistage sampling procedure from two local governments where coffee was grown in commercial basis. The result revealed that most (90%) male dominated coffee farming, 74% were literate and mean age of farmers was 41.4 years. The major sources of information on coffee production technologies utilization was from input dealers (68%). very few farmers (26%) had contact with extension agent. The result also revealed overall categorization of farmers into level of utilization of coffee production technologies with majority (61%) indicating low level of utilization. There was significant relationship between age (X^2 =8.61, p=0.01), sex (X^2 =14.19, p=0.00), and extension contact (X^2 = 14.19, p = 0.00) and coffee production technologies utilization. It was concluded that extension agent should improve on their contact with farmers which will lead them to get information form the right source

Key words: Cocoa farmers, Information, production technologies, utilization

INTRODUCTION

Coffee is one of the important commercial plantation crops grown in Nigeria which is ranked second in value only to oil as a source of foreign exchange in many of the major producing countries, Nigeria inclusive (Opeke, 2005). The two most important species of cultivated coffees in Nigeria are Arabica coffee (highland coffee) and Robusta coffee, lowland coffee (Agbongiarhuoyi et al., 2006). Over 80% of coffee from developing countries particularly Nigeria, is produced by small scale farmers who lack adequate technical education and are faced with low market prices leading to poor management, poor productivity and abandon farms. In about 50 countries of the world, almost 25million farmers depend on coffee as a mean of survival (Cague et al., 2009). Coffee channel of production and marketing provide employment for millions of people throughout the world. Despite the facts that coffee production can boost the country's revenue, coffee production is fast declining because farmers are no longer interested in its production in Nigeria (Ayoola et al., 2012). On that basis, Cocoa Research Institute of Nigeria (CRIN) with research mandate on cocoa, kola, coffee, cashew, and tea has recommended some coffee production technologies that can help coffee farmers to boost their production if adhere strictly to it. Some of these recommended coffee production technologies are; site selection/land preparation, use of improved coffee varieties, shade management, planting period and spacing (3m x3m), control of pest/insect and pathogens, regular weeding, coffee rehabilitation, gapping up of missing/death stands, regular pruning, appropriate fertilizer application and timely harvesting/processing (CRIN, 2018). Uwagboe et al. (2006) as quoted by Adeogun et al. (2010) stated that the best way to pass information on new technologies and innovations to a larger proportion of farmers is through personal contacts such as visits from extension agents. According to Israel and Wilson (2006) and Oto and Shimayohol (2011), developing an understanding of extension sources and channels used by clients to obtain information is a pre-requisite for efficient educational programming because messages that go unheard or unseen cannot lead to change. The awareness and utilization of these coffee production technologies will not only increase farmers' income but also improve their standard of living. Hence, this study assessed the information sources to coffee farmers on coffee production technologies utilization

The specific objectives are to:

(1) Determine the socioeconomic characteristics of the respondents

(2) Investigate the sources of information on coffee production technologies utilization

(1) Examine the level of utilization of coffee production technologies

Hypothesis of the study.

There is no significant relationship between socioeconomic characteristics of the respondents and sources of information on coffee production technologies

MATERIALS AND METHODS

A multistage sampling procedure was used to select farmers for the study. The first stage involves the selection of Kogi State because it is the highest producer of coffee Robusta in Nigeria. The second stage involves random selection of two (2) Local Government Areas which are Kabba-Bunu and Ijumu as a result of their prominence in coffee production. Two (2) villages were purposively selected from each local government due to coffee production activities in large quantity making a total of four (4) villages. Twenty-five (25) farmers were randomly selected in each village to make a total of sample size of one hundred (100) respondents. Data for the study was collected through the use of well-structured questionnaire and interview schedule. Descriptive statistics such as frequency counts, percentages and means were used to analyze the objectives while the hypothesis was tested with chi-square

RESULTS AND DISCUSION

Socioeconomic characteristics

The socioeconomic characteristics of respondents are shown in table 1. The result shows greater percentage (90%) of the respondents were male while only 10% were female. It means that more males were into coffee farming in the study areas. It shows that coffee farming is very tedious activity that can be carried out by male. This is in agreement with Oladipupo et al. (2010) that farm work is mostly being carried out by men because they have strength to withstand the rigours of farming activities. The result also shows that 85% of the respondents were married with mean ages of 41.4 years. The implication of this is that coffee farmers in the study area are still in their productive and energetic age. The mean household size for the farmers was 7.8 persons. Household size provides cheap labour for agricultural purposes. The table also revealed that farmers' extension contact was very low with majority (74%) not having contact while only 26% had contact. This result is in tandem with Famuyiwa et al. (2014) that 84.3% of farmers had no extension contact. When farmers have regular contact with extension agent, then there will be information flow. Farmers will present their production problems to extension agents likewise extension agents bring information on new technologies to farmers. when there is a gap between extension agent and farmers, there will be lack of information and consequently affecting adoption of new technologies by farmers

Table 1: Distribution of respondents by socioeconomic characteristics

Variables	Frequency	Percentage	Mean
AGE			
<30	16	16	
31-40	17	17	41.4 years

Table 2 shows level of education of the respondents that 26% of respondents had no formal education while 29% of the respondents had primary education, 30% are school certificate holders, and 15% attended tertiary institutions. It shows that 74% of the respondents can read and write. There is high level of literacy among farmers in the study areas this will to greater extent influenced them positively in adopting new technologies.

Table 2: Distribution of the respondents based on level of education

Farmers educational status	Frequency	Percentage
No formal education	26	26
Primary education	29	29
Secondary education	30	30
Tertiary education	15	15
Total	100	100

Source: Field Survey; 2021.

Tables 3 shows that majority (68%) get information from input dealers, 15% get information from coffee farmers' association of Nigeria, 19% get information from extension agents while only 20% get information from research institutes. information, according to oxford dictionary is facts provided or learned about something or someone. It shows that farmers did not get information from the right sources. This will affect their utilization of coffee production technologies. This result is in agreement with the findings of Adeogun et al. (2010) that majority of farmers obtained information on rehabilitation technique through radio which is not the best source to obtain such information. Information on coffee production technologies is best gotten from research institute (CRIN) because it involves training of farmers on the best way to practice it.

The results in table 4a show mean rank order of farmers' utilization of coffee production technologies with regular pruning(mean=2.64) ranked 1^{st}. It follows by gapping up of missing/death stands (mean= 2.63), shade management (mean = 2.43), planting distance (mean =2.29), with ranked 2^{nd} ,3^{rd}, and 4^{th} order of utilization. Other coffee production technologies utilized by farmers are timely harvest/processing (mean =2.16) which ranked 5^{th}, use of improved coffee varieties (mean =2.14) which ranked 6^{th} it follows by control of pest insect and pathogens (mean =2.06), site selection (mean =2.03), appropriate fertilizer application (mean =2.01) and coffee wet processing method (mean =1.06) ranked 7^{th}, 8^{th}, 9^{th} and 10^{th} order of utilization.

Timely harvest/processing	2.16	5th
Coffee wet processing method	1.06	10th

Source: Field Survey 2021.

Farmers level of utilization of coffee production technologies was categorized into low and high (Table 4b). This was determined as the mean level of utilization scores were computed and used as the benchmark, such that respondents whose scores are below the mean level of utilization scores were categorized as low utilization, while scores equal to or greater than the mean score were categorized as having high utilization. The result shows that majority (61%) of the respondents had low utilization of coffee production technologies while only 39% had utilization of coffee production technologies. The low utilization of coffee production technologies could be as a result of not getting information from the right sources

Table 4b: Level of utilization of coffee production technologies

Interpretation	Frequency	Percentage
Low	61	61
High	49	39
Total	100	100

Hypothesis testing

Chi-square result of the relationship between respondents selected socioeconomic characteristics and information sources to coffee production technologies as revealed in table 5. It shows a significant relationship occurred between age (X^2 = 8.61; P< 0.01), Sex (X^2= 10.19; P< 0.00), and extension contact (X^2=14.19; P=0.00) and information sources to coffee production technologies. It implies that age directly influences

ISSN: 2814-0508

information sources to coffee production technologies. The younger farmers are still very energetic and can go a long way in searching for information that will improve their production. On significant relationship between sex and information sources, women are constrained to stay at home to take care of the family whereas his male counterparts enjoy more freedom to get information anywhere that will improve their coffee production. Also, on significant relationship between extension contact and information sources, the more contact of extension agent with the farmers the more they may likely get information on coffee production technologies and vise vasa. From the findings, extension contact with farmers was low which resulted to low utilization of coffee production technologies.

Table 5: Chi square showing test of significant relationship between some selected socioeconomic characteristics and sources of information on coffee production technologies utilization

Socioeconomic characteristics	X^2	Df	P-value	Decision
Age	8.61	2	0.01	S
Marital status	2.99	2	0.23	N S
Religion	5.30	3	0.15	N S
Sex	10.19	1	0.00	S
Extension contact	14.19	3	0.00	S
Household size	3.88	3	0.28	N S

Source: Field Survey 2021.

CONCLUSION AND RECOMMENDATION

The study revealed that most coffee farmers are male and are still very active in farming business. It also revealed that most of them are literate i e they can read and write. There was low extension contact with farmers as the study revealed that most coffee farmers were not visited by extension agent. The major sources of information on coffee production technologies was through input dealers. There was low utilization of coffee production technologies, this may be as result of not getting information from the source. There was significant relationship a between age, sex, extension contact and coffee production technologies utilization. Extension agent should increase their visit to coffee farmers so that they can get information from the right source this will increase the utilization of this technologies among coffee farmers

ABSTRACT

Ornamental plants have the ability to enhance the entire ambience and improve the topography of a place. Although they are grown basically for decorative and aesthetic purposes, they also have nutritive and medicinal properties. The proceedings of Horticultural Society of Nigeria (HORTSON) of the years 2009-2020 was selected as the source of citation data for this study. Articles on ornamental plants published were analysed. Data collected from the articles included: types of ornamental plants researched, number of citations, number of author(s), authors' affiliation, and pattern of authorship. Descriptive statistics were used to analyse the data. The result of the study revealed high degree of collaboration among horticultural scientists in the research institutes, Universities and colleges of agriculture. The authorship pattern shows majority of joint authorship. Contributions from various research Institutes in Nigeria was the highest (59.7%) followed by authors from Universities (21.3%). National Horticultural Research Institute had the highest contributions (96.8%) among other research institutes. While Federal University of Agriculture, had the highest contributions among other universities (66.6%).

Key words: Ornamental; Collaboration; Citations; Authorship; Nigeria

INTRODUCTION

Collaboration is working together as a team to achieve a purpose. "Authorship is one aspect that plays a great role in information dissemination and communication. Authors' contribution to the field of knowledge could be viewed from different patterns, such as single authorship, joint authorship and multiple authorship'' (Aliyu, 2011). The authorship pattern analysis elucidates the work of Scientists contribution to the number of papers at a certain time. (Sankar and Srinivasa ,2012). Singh and Singh (2018) investigated the trends in authorship pattern and author collaborative in the Biotechnology research field. Their study revealed that the researchers in Biotechnology move towards team research or group research rather than solo research. Viswanathan and Tamizhchelvan (2016) examined authorship productivity and collaborative nature on spacecrafts research outputs during the period 2000 and 2014.The result of their study revealed that most of the researchers in this field preferred a collaborated work. There has not been any bibliometric documentation on ornamental horticulture in Nigeria.This study aims to find out the trend of research collaboration in the field of ornamental horticulture.

MATERIALS AND METHODS

The Proceedings of Horticultural Society of Nigeria (HORTSON) of the years 2009-2020 was selected as the source of citation data for this study. Articles on ornamental plants published were analysed. Data collected from the articles included: types of ornamental plants research, number of citations, number of author(s), authors' affiliation, and pattern of authorship. Descriptive statistics were used to analyse the data.

RESULTS AND DISCUSSION

A total number of forty-four (44) papers were published in the HORTSON Proceedings on ornamental plants/landscape between 2009 to 2020. No HORTSON Proceedings was published in 2013. There was no research article on ornamental plants/landscape in the HORTSON Proceedinsg of 2010. Year 2019 had the highest number of publications on ornamental plants/landscape (Table 1). Papers with three authors had the highest number of publications (Table 2). Table 3 shows authors with frequency count of five or more on Ornamental/Landscapes. Table 4 indicates that National Horticultural Research Institute (NIHORT) contributed the highest number of authors 122 (96.8 %) among the research institutes from 2009-2020. Federal University of Agriculture Abeokuta contributed the highest number of authors 30 (66.6 %) among the universities in Nigeria (Table 5, 6). The following ornamental plants were identified in HORTSON proceedings in years 2009-2020: *Heliconia* (cv. 'Golden Torch') Flowers, *Begonia semperflorens,* Sunflower *(Helianthus anuus* L.), *Callitris mantis* (cypress-pine), *Senna fistula* (Golden shower), Flamingo flower (*Anturrium andraenum* L.), Marigold (*Tagetes spp*), Purple rose periwinkle (*Catharantus roseus* L.), Heliconia (cv. "golden torch") and Duranta (*Duranta erecta*)

CONCLUSION

The study revealed collaboration of authors from research institutes, universities and colleges of agriculture working together on ornamental plants. The highest numbers of research articles were published in 2019.The scientists in the field of ornamental horticulture need to work more on other ornamental plants and also collaborate with foreign authors.

ABSTRACT

Agricultural research is saddled with the responsibility of addressing the monumental challenges of agriculture to ensure that its diverse benefits translate into increased productivity and improvement in the living conditions of stakeholders. Greater efficiency, transparency and accountability in research is required as sharp practices do not only tarnish the credibility and integrity of the researcher and research institution, they affect the multitude of the citizens as food and health policies for the citizenry are based on evidence of agricultural research. The study was undertaken to assess the involvement in sharp practices of research personnel in agricultural research institutes in south western Nigeria. Both quantitative in form of questionnaire and historical were used for data collection. Multistage sampling procedure was used to select a sample of 30 respondents in the study area. The result of the findings was analysed using descriptive statistics such as frequency and percentages. The study revealed that 48.0 % of the respondents were between the age of 30 and 39, 64.0% were male and majority (92.0%) were married. The result further revealed that 40.0% of respondents were in the senior research cadre and majority (84.0%) were aware of fabrication of data as a sharp practice. Only 12.0% were involved in extrapolation of data. Ethical standards should be vigorously adhered to in order to limit sharp practices among research personnel.

Key words: Research misconduct, Horticulture, Agricultural Policy, Nigeria

INTRODUCTION

Agriculture apart from being the catalyst for economic growth provides food, clothing, employment, tourism for the over 160 million people in Nigeria and significantly contributes to the alleviation of poverty and promotes international competitiveness (Food and Agriculture Organization, 2012). Agriculture remains the economic base for Nigeria as it significantly contributes to poverty reduction and sustainable development; provides 35.1%in 2019 (World Bank Report, 2020) percent of employment and is a major determinant of aggregate economic growth, accounting for 42 percent of GDP growth (NBS, 2006). Despite the country's huge dependence on the oil and gas sector agriculture is its mainstay offering important investment opportunities at all levels of economic and sustainable rural and national development (Aminu and Anono, 2012). In Nigeria as well as other developing countries, most agricultural production comes from small-scale farms and low-income farmers. These farmers reside in rural areas, where they depend directly or indirectly on agriculture for their livelihood (FAO, 2012). The food security and nutritional status of Nigerian households therefore depend on agricultural production.

Agricultural research for development

Agricultural Research for Development (ARD) is a multi-dimension's research that addresses the agricultural development challenges of developing and emerging countries (SFIAR Award 2021 - Guidelines). The agricultural domain includes crop production and animal husbandry, agro-forestry, fisheries and aquaculture, agribusiness and related enterprises, animal and human health related issues, as well as the sustainable management of the natural sources on which farming depends and the socio-cultural and bio-diverse landscapes, food systems and ecologies in which it is embedded (SFIAR Award 2021 - Guidelines). Research which is the process of arriving at dependable solutions to problems through a planned and systematic collection, analysis and interpretation of data is the bedrock of policy formulation (Amzat and Ogundiya, 2010). Research is the most important tool for advancing knowledge, for promoting progress and enabling man to relate more effectively to his environment, to accomplish his purpose and to solve his conflicts (Okoro, 2013).

ARD provides technological, economic and institutional knowledge and innovations contributing to sustainable development by solving the food and nutrition challenges confronting the human society. The thrust of agricultural research therefore is in solving problems of poverty, hunger, food and nutrition security by improving productivity and income; minimizing the effects of pests- weeds, insects, pathogens, nematodes on crops and livestock and the prevention and correction of adverse environmental effect. A policy which is a plan of action adopted by a Government in order to influence the trend of events in order to achieve a set of objectives () is usually based on theoretical and empirical evidence from research. The evidence from research are crucial in evaluating, modifying or changing policies in order to address the established problems.

National Agricultural Research Systems (NARS)

These are the building blocks of the global ARD system. They include various stakeholders such as National Agricultural Research Institutions (NARIs), Universities, NGOs, Extension services, farmer's organisations, farmers, private sector with the primary responsibility for generating, adapting and transferring technologies that farmers need to ensure food security and equitable, sustainable development. NARIs often occupies a prominent position in expressing national research priorities and in setting up and implementing the national research agenda.

The agricultural sector, however, faces monumental challenges such as adaptation to the vagaries of climate change, crop production to meet the needs of the biofuel industries as well as for food security, nutrition, biosecurity. The solutions however lie veiled in the complexity of the findings of research efforts in the midst of limited resources. The contribution of the agricultural sector to the accelerated and transformative growth initiative requires focused effort in tackling and responding to identified challenges and opportunities which requires a core of competent researchers to generate knowledge to achieve sustainable natural resource utilization, manage biodiversity conservation; develop risk-management strategies for agricultural production to address natural disasters, climate change and disease and pest outbreaks; improve production systems, post-harvest and processing technologies to enhance nutrition, food security and safety. One of the objectives of agricultural development therefore is to maintain and retain a cadre of qualified, experienced, motivated and competent agricultural R&D personnel that can achieve the long-term goals of food security and poverty alleviation, international competitiveness in agriculture and enhancement and sustainability of the natural resource base. This would ensure that important policies to address these challenges facing the human society are formulated from the evidence and findings of these seasoned crop of research personnel.

Sharp practices (scientific or research misconduct)

Sharp practices in research which could be regarded as research or scientific misconduct is defined as the intentional distortion of the research process by fabrication of data, text, hypotheses or methods from another researcher's manuscript form or publication or distortion of the research process in other ways (Wikidoc, 2012). Also refers to an intentional fabrication, falsification or plagiarism in proposing, performing or reviewing research or in reporting research results which must be proven by sufficient evidence. Sharp practices include breaches of confidentiality and authorship or publication violations.

Research results are reported as manuscript or theses given to a mentor as representing the result of experiments; reports submitted such as progress reports in renewal applications; application for continuing years of an approved project; preliminary data in new grant applications and as abstracts, posters, oral presentations or preliminary reports presented at scientific meetings.

This is the similar trio- fabrication, falsification and plagiarism (referred to as "FFP" in international discussion.

Sharp practices in research include:

Fabrication The practice of generating data without performing the relevant research; i.e. making up results and recording or reporting them**.**

Falsification Manipulating research materials, equipment or processes or changing or omitting data or results such that research is not accurately represented in the research record.

Plagiarism The appropriation of another person's ideas, processes, results or words without giving appropriate credit.

Citation plagiarism Also known as citation amnesia, bibliographic negligence or disregard syndrome is the willful or negligent failure to appropriately credit other or prior discoveries so as to give an improper impression of priority.

Plagiarism fabrication The act of taking an unrelated figure from an unrelated publication and reproducing it exactly in a new publication with the claim that it represents new data.

Self-plagiarism Also known as recycling fraud is the reuse of significant, identical or nearly identical portion of one's work without acknowledging that one is doing so or without citing the original work. Articles of this nature are referred to as duplicate or multiple publication.

ISSN: 2814-0508

Ghost writing When the real author is not listed as an author

Suppression of research The failure to publish significant findings due to the results being averse to the interests of the researcher or his/her sponsors.

Extrapolation of data

Sabotaging others research

Guest authorship where there is stated authorship in the absence of involvement

Honorary authorship Listing an individual as an author as a sign of respect or gratitude.

Gift authorship Listing an individual as an author as a personal or professional favor or for reciprocal co-author arrangement.

Prestige authorship Listing an individual with a high degree of notoriety as an author to give the publication more visibility or impact.

Massaging data picking and choosing data that support your argument while ignoring those that do not (Bornmann, 2013.*)*

Consequences of sharp practices in Agricultural Research

The enormousity of the consequences that can happen when flawed research is added to the body of knowledge or is used in policy formulation cannot be overemphasized. It is in line with these that this study was undertaken to examine the aforementioned sharp practices as detrimental in achieving the objectives of agricultural research.

The general objective of the study is to ascertain involvement in sharp practices among research personnel in agricultural research institutes in South Western Nigeria. The specific objectives of the study are to:

1. Identify the personal characteristics of research personnel in the study area;
2. Ascertain research personnel's awareness of sharp practices in research;
3. Determine the respondents' involvement in sharp practices;

MATERIALS AND METHODS

Study area

The study was carried out in National Horticultural Research Institute (NIHORT), Ibadan South Western Nigeria. NIHORT Ibadan started as "The National Fruit and Vegetable Research and Development Centre (NFVRDC)" with the assistance of UNDP/FAO project NIR/72/007. By the Federal Government Agricultural Research Institute Establishment Decree Order No. 35 of June 1975, the center metamorphosed into the "National Horticultural Research Institute (NIHORT)" along with other Agriculture Research Institutes. With the promulgation of decree No. 5 in January 1977, the Institute came under the National Science and Technology Development Agency (NSTDA). In January 1980, the Science and Technology Bill of 1980 transferred the Institute to the Ministry of Science and Technology. However, since 1996, it has been under the Federal Ministry of Agriculture and Rural Development. Following the Agricultural Research Council of Nigeria Act 1999 (hereinafter referred to as "the principal Act to further the advancement of research, training and extension in the agricultural Research, the Institute thus came under the Agricultural Research Council of Nigeria (ARCN) in 2006.

A multi-stage sampling technique was used to select the respondents for the study. The first stage involved a purposive selection of one (1) out of the three (3) agricultural research institutes (ARIs) in the south western zone of Nigeria. NIHORT was randomly selected.

The second stage involved a purposive sampling of the Research personnel in the institute. Research personnel on research cadres Research Officer 1 to Assistant Directors were selected for the study. Research Officer 11 who are still newly employed and Research Directors were excluded from the study.

The third stage involved a random selection of 40% of officers from the selected cadre (RO 1 to Assistant Director of Research). Thirty Research personnel were therefore randomly selected for the study.

Data for this study was collected through the use of structured questionnaire and were analyzed using descriptive statistics such as frequency and percentage counts to describe the variables in the specific objectives of the study.

RESULTS AND DISCUSSION

Personal characteristics of respondents

Results in Table 1 showed that 48.0% of the respondents were between the ages of 30 – 39 while 36.0% were between the age brackets of 40 – 49. This implies that most of the respondents are still energetic and with young mind for agricultural research. Also, 64.0% of the respondents were male while only 36.0% were female. This indicates that there are more males than females which may be attributed to the physical nature of agricultural

ISSN: 2814-0508

research coupled with very frequent travels of researchers.

The study also showed that 92.0% of the respondents were married while only 8.0% were single. This showed that a very large proportion of the respondents were married and therefore are responsible and settled individuals which is a crucial attribute required for success in research. Findings from the study also revealed that 96.0% of the respondents have less than 9 persons in their households. This indicates that a very large proportion of the research personnel have small family size with a limited number of persons who depend on them. The study revealed that only 12.0% of the respondents had only BSc degree; 48.0% had MSc, 8.0% had M Phil and 32.0% had PhD degree. This result is an indication that the respondents are academically progressive which could be attributed to higher qualifications being a pre-requisite for progression in research career. Majority (40.0%) of the respondents were in the Senior Research cadre. 20.0% of the respondents were in the Research Officer 1 cadre with 32.0% in the Principal Research cadre. Only 4% were in the Chief Research cadre; 4.0% in the Assistant Director cadre. No Director was involved in this study.

Table 1: Percentage distribution on Personal characteristics of respondents

Variables	Percentage
Age	
30-39	48.0
40 – 49.	36.0
Sex	
Male	64.0
Female	36.0

Senior Research cadre	40.0
Research Officer 1 cadre	20.0
Principal Research cadre	32.0
Chief Research cadre	4.0
Assistant Director cadre.	4.0

Respondents' awareness of sharp practices in research

The result (Table 2) reveals that 84.0% of respondents are aware of fabrication of data, Plagiarism, Falsification of data, Extrapolation of data, while 72.0% are equally aware of Suppression of data and Self-plagiarism as types of sharp practices in research. This is an indication that respondents are very much aware of sharp practices that goes on in research. This is in line with the studies of Bamigboye and Oladosu (2015) who opined that 68% of farmers were aware of sharp practices involved in Agricultural mechanization.

Table 2: Respondent's awareness of sharp practices in research

	Sharp practice	Rank	Percent*
1	Fabrication of data	*1*	*84*
2	Plagiarism	*1*	*84*
3	Falsification of data	*1*	*84*
4	Extrapolation of data	*1*	*84*

*multiple responses

Respondent's involvement in sharp practices

The result shows (Table 3) that 28.0%, 16.0%,12.0% are involved in withdrawal of publication, guest/honorary authorship, massaging data and extrapolation of data respectively. The result indicated that the involvement of researchers in sharp practices is not so high though they are involved.

Table 3: Respondent's involvement in sharp practices

CONCLUSIONS

The study established that there were few female research personnel in the National Horticultural Research Institute and that a large proportion of research personnel at large are relatively young which implies that research has a promising future. The study also revealed that although the level of awareness of the diverse sharp practices in research among research personnel is high; their level of involvement in these sharp practices is very low.

RECOMMENDATIONS

Based on the findings of the study, the following recommendations are made:

1. More females should be encouraged in the field of agriculture and in agricultural research particularly;

2. Penalties should be attached to research misconduct and sharp practices;

3. The NARIs /ARCN should encourage research personnel to regard success in research as key to citizens wellbeing and not merely for promotional benefits or for career progression.

Researchers themselves have a duty to conduct themselves with integrity in their research work. Integrity should be second nature to researchers. Integrity is vital to fostering trust that researchers have in one another and the trust that society places in the result of their research. Research institutes are responsible for paying attention to integrity in research practice

ABSTRACT

Access to viable information by farmers in this era of climate change is very crucial to cocoa production. The study therefore examines the various sources of information available to farmers on climate change and their challenges on Cocoa Insect Pest control amongst smallholder cocoa Farmers in Cross River State. Multi stage sampling procedure was used to select 132 respondents from three local Government Areas (Etung, Boki and Ikom). Interview schedule and questionnaire administration for data collection on personal characteristics of the cocoa farmers, sources of climate change information, types of agro-climatic change information, quantity of cocoa beans in bags produced by farmers, constraints encountered in coping with climate smart adaptation strategies. Data were analysed using descriptive statistics such as frequencies and percentages while inferential statistics used was Pearson Product Moment Correlation (PPMS). Results revealed that 12.9% were below the age of 30 years, 56.8% of them were between the ages of 31-50 years, 25.8% of the respondents were between the ages of 51-70 while only a few 4.5% were between the ages of 71-90. The mean age of the respondents was 45 years. Their major information source is from friends and family with 23.5% and the major constraint was high cost of pesticides 88.7% in climate change adaptation. The highest constraint of the respondents was high cost of pesticides 88.7%. Frequency of climate change information obtained on insect pest and diseases of respondents positively correlated with their constraints encountered in adapting to climate change strategies ($r = 0.361$, $p < 0.05$). In conclusion, the study has shown that majority of the respondents' major channel of information was family and friends not through extension agents and CRIN. Therefore, there is the need for an urgent strengthening of extension arm of CRIN and Nigeria in general.

Key words: Climate change, constraints, information channels, Cocoa farmers

INTRODUCTION

Climate change is defined as change in the state of the climate over time, either due to natural variability or as a result of human activities resulting to most of the global warming that persist over an extended period typically decades (IPCC,2011). Globally, climate change has been described as an important determinant of abundance and distribution of species and it possesses potential threat to environment and agricultural production which has implications on livelihood of farmers.

Information and communication are essential ingredients in the transfer of developed technologies such as climate change adaptation strategies designed to boost agricultural production. In order for farmers to benefit from such, they must first have access to the technologies and learn how to effectively utilize same in their farming systems and practices (Ani and Baba, 2009). Extension agents play a major role in transferring information on climate change and improved agricultural practices to the end users through media and participatory training approach. It serves as a source of advice and assistance for farmers in order to respond proactively to climate change and improving their production and marketing (Adams, 1988). The level of public awareness on issues related to climate change in Nigeria is considered to be low (BNRCC, 2011), however access to specific weather information, early warning systems and forecast technologies can also help farmers to develop and readjust coping or adaptation strategies (Otitoju and Enete, 2016)

Prior to the discovery of oil and gas, the agricultural sector was the backbone of the Nigerian economy though it has been affected by climate change. However, there is dearth of information on the farmers' perception on climate change affecting agricultural productivity, such as changes in weather patterns and extreme weather impacts on livestock and crop production. Understanding farmers' knowledge and sources of information will help improve on current economic, social and environmental risk polices mitigating and adapting to climate change (Deressa, 2009). The challenges of climate change such as increasing temperature, change rainfall pattern, soil depletion, pests and disease have negative resultant effect on agricultural activities thus posing new risk challenges to food production (Neate, 2013). These adverse events and challenges have led to reduce income, fall in farm practices and welfare of farming households (Lawal, 2016). Farming activities shudders such as heavy rains, flood, price and income fluctuations both eccentric and covariate in nature are globally predominant and they are particularly arduous to small-scale farmers in developing countries. Therefore, farmers' attitudes and opinions towards climate change can help improve policies and decision-making at local level. Consequently, the principal focus of this research paper is on the challenges faced by farmers through the investigation of farmers' knowledge on channels of information, types of agro-climate change information and the effects of climate change on spread of insect pests and diseases which pose threats to increased cocoa production.

Objectives of the study

This study has the following objectives:

i. To identify farmers' personal characteristics in the study area.

ii. To examine the sources of information on climate change.

iii. To identify the types of climate change information available to farmers

iv. To find out the constraints in the utilization of climate change information.

MATERIALS AND METHODS

A multi-stage sampling procedure was used in the selection of the local government areas, communities and the cocoa farmers. In stage 1: Three (3) Local Government Areas (LGA) were selected. In Stage 2: Three (3) communities were selected based on contiguity and proximity to the farmers' centers as follows**:** 1) Etung LGA: Ajassor, Etomi and Effraya, (2) Ikom LGA: Okundi, Ekonde and Akparabong and 3) Boki L.G.A: Olom, Nsadop and Iruan. Stage 3: In the communities, farmers were selected from Etung LGA Fifty (50) farmers, Boki LGA Forty-two (42) while in Ikom LGA Forty (40) farmers were selected giving a total of 132 cocoa farmers.

RESULTS AND DISCUSSION

Table 1 revealed the personal characteristics of the respondents as majority (81.1%) of the respondents were males while 18.9% were females. This implies that men in the study area were more involved in cocoa production than the women which support Uwagboe and Agbongiarhuoyi, (2020), where most cultures in Nigeria limit women in acquiring land for tree crops cultivation which however affects their technology adoption. Respondents' age revealed that, (12.9%) were below the age of 30 years, (56.8%) of them were between the ages of 31-50 years, (25.8%) of the respondents were between the ages of 51-70 years while (4.5%) were between the ages of 71-90 years. The mean age of the respondents was 45 years, as farmers below the mean age were seen younger, while those above the mean age were older farmers. In all, (69.7%) were within mean age of the respondents which corroborates the findings of Akinbile and Ndaghu (2005) where, most farmers were between the ages of 20-50 years and very active farmers to seek information on climate change. All the farmers had one form of the formal education based on the number of years spent in school (37.1%) of the respondents had primary education, (44.7%) of them attained secondary education while (18.2%) had tertiary education, totaling (77.2%) which corroborates the findings of Edeoghon *et al.,* (2008) that education is a panacea to boost agricultural production.

Table 1: Personal characteristics of respondents (N=132)

Sex	Frequency	Percentage	Mean
Male	107	81.1	
Female	25	18.9	
Age			45.0 years
11-30	17	12.9	
31-50	75	56.8	
51-70	34	25.8	
71-90	6	4.5	
Years spent in school			
1-6	49	37.1	
7-12	59	44.7	
13-18	24	18.2

Table 2 shows the farmers response on their channels of climate change information which help in taking decisions on when and type of crop to plant and ditto the kind of animal production to engage in. The climate change information gives scientific direction on the kind of practice in every farming season. Farmers received climate change information from different sources such as relatives

ISSN: 2814-0508

(23.5%), fellow farmers (21.9%), CRIN channel (15.2%), extension agents (9.8%), NIMET (6.8%), Radio channels(9.1%),phone messages(7.6%),television(6.1%) this is contrast tothe findings of Csoto (2010), where radio, extension services and television were majorly used in rural areas to access climate, especially radio information resulting from the affordability and size of the gadget as been able to fix up in the clothing pockets.

Table 2: Respondents' sources of climate change information

Channels	Frequency	Percentage
Friends and family	31	23.5
NIMET	9	6.8
CRIN	20	15.2
Radio	12	9.1
Television	8	6.1
Phone	10	7.6
Fellow farmer	29	21.9
Extension Agent	13	9.8
Total	132	100.0

Source: Field Survey, 2019

Table 3 indicates types of agro-climate change information accessed by farmers in the study area. Based on these findings, farmers accessed different forms of information on climate change in order to allow them to take decisions on how to effectively control insects' infestation and diseases and infection. This table highlights the percentage of respondents who accessed different kinds of climate change information, (66.7%) of the respondents have access to early warning signals information, (68.9%) seasonal rainfall, (56.0%) seasonal temperature forecast, (32.6%), insect pest, diseases prevalence and drought (28.0%). These various types of climate change information stated above are required by farmers on how to adapt and mitigate climate change effects which has posed a very big threat to food security and achievement of agricultural diversification programme (Chukwuji, *et al*., 2019). It takes information to make a right or an informed decision. In the face of the threats posed by climate change to the world especially Nigeria, there is need for adequate and timely information to be given out to the public. This information will help the people especially the vulnerable to build capacity for adaptation and or mitigation of the effects of climate change. Idoma and Mamman (2016) in their study revealed that early warning signals, rainfall prediction, drought prediction, adaptation technology, food aid, temperature change are needed climate change information and knowledge which require sharing between scientists, farmers, policy makers and community institutions in order to enhance practical adaptation at the grassroots level.

ISSN: 2814-0508

Table 3: Types of Agro-climate information received on insects' pest and diseases of cocoa

Types of information	Yes		No	
	Frequency	Percentage	Frequency	Percentage
Early warning signals	88	66.7	44	33.3
Seasonal rainfall prediction	91	68.9	41	31.1
Seasonal temperature forecast	74	56.0	58	44.0
Insect pest and diseases population data	43	32.6	89	67.4
Drought	37	28.0	95	72.0
Climate change impact zones in Cross River State	57	43.2	75	56.8

Source: Field Survey, 2019

Table 4 reveal that the most critical constraint among the respondents in coping with climate change in the study area was high cost of pesticides (88.7%), financial constraints was (83.3%), inadequate climate change information (54.5%), high labour cost as very serious constraint responses was (75%), the constraint of respondents on emerging pests was (41.7%), which could have adverse effects on cocoa production and reduce yield leading to low income.

Table 4: Challenges encountered in coping with climate smart adaptation strategies

Constraints	**Very serious**		**Serious**		**Not serious**	
	Frequency	**Percentage**	**Frequency**	**Percentage**	**Frequency**	**Percentage**
High cost of pesticides	117	88.7	13	9.8	2	1.5
Labour cost	99	75.0	32	24.2	1	0.8
Financial problem	110	83.3	19	14.4	3	2.3
Inadequate climate change information	72	54.5	36	27.3	24	18.2
Emerging or new pest problem	55	41.7	34	25.8	43	32.6

Source: Field Survey, 2019

Table 5 shows that channels of climate change information obtained on insect pest and diseases of cocoa by respondents, positively correlated with the constraints encountered in adapting to climate change strategies ($r = 0.361$, $p < 0.05$). This is an indication that channel of climate change information obtained had significant relationship with farmers' constraints encountered in adapting to climate change strategies. According to Mark (2008) some of the direct impacts of climate change on agro-climatic conditions include alteration in rainfall and temperature, growing seasons, planting and harvesting calendars, water availability, pest, weed and disease populations. However, the findings of Onyeneke (2010) indicated majority of smallholder farmers' suffered knowledge gap in coping with climate change adaptation strategies due to lack of adequate information on climate change, while Nwaru (2004) and Aderinto *et al*. (2009) in a different study observed that poor financial position of the peasant farmers compels them to produce on a very small scale and so earn relatively small income.

Table 5: Correlation between climate change information sources and challenges encountered by farmers in adapting to climate change strategies

Variable	R	P	Decision
Climate change information on insect pest and diseases	0.361	0.000	Significant

*Pearson Product Moment Correlations. Source: Field Survey, 2019

CONCLUSION AND RECOMMENDATIONS

This study examined the various sources of information available to farmers on climate change and their challenges on Cocoa insect pest control amongst small-holder's cocoa farmers in Cross River State. This investigation revealed more men in the active mean age of 45 years obtain information on climate change than women, despite that the farmers involved had different forms of formal education as determined by the number of years spent in school, however secondary sources of information from co-habitat have been the major channel of climate change information and prominent amongst the sources of information is that of seasonal rainfall prediction, while in addition is the high cost of pesticides. There is an indication that channel of climate change information obtained had significant relationship with farmers' constraints encountered in adapting to climate change strategies. Therefore, there is the need for an urgent strengthening of extension arm of institutions of relevance as a channel of information on cocoa climate change making the power of information incontrovertible

ABSTRACT

Guava (Psidium guajava) is a well-known tropical tree abundantly grown for fruit. Many countries have a long history of using guava for medicinal purposes. This plant is used for the treatment of diarrhea, dysentery, gastroenteritis, hypertension, diabetes, caries and pain relief and improvement in locomotors coordination. Its leaf's extract is being used as a medicine in cough, diarrhea, oral ulcers and in some swollen gums wound. Its fruit is rich in vitamins A, C, iron, phosphorus and calcium and minerals. It contains high content of organic and inorganic compounds like secondary metabolites such as antioxidants, polyphenols, antiviral compounds, anti-inflammatory compounds. The phenolic compounds in guava help to cure cancerous cells and prevent skin aging. The presence of terpenes, caryophyllene oxide and p-selinene produces relaxation effects. Guava leaves contain many compounds which act as fungistatic and bacteriostatic agents. Guava has a high content of important antioxidants and radio-protective ability. Quercetin is considered as most active antioxidant in the guava leaves and is responsible for its spasmolytic activity. Its ethyl acetate extract can stop the germ infection and thymus production. Guava possesses anti-viral, anti-inflammatory, anti-plaque and anti-mutagenic activities. Guava extract shows antinociceptive activity and is also effective in liver damage inflammation and serum production.

Key words: Medicinal potentials, chemical properties, *Psidium guajava*

INTRODUCTION

The guava (*Psidium guajava L.*) tree belonging to the *Myrtaceae* family, is a very unique and traditional plant which is grown due to its diverse medicinal and nutritive properties. Guava has been grown and utilized as an important fruit in tropical areas like India, Indonesia, Pakistan, Bangladesh, and South America. Different parts of the guava tree - roots, leaves, bark, stem, and fruits, have been employed for treating stomachache, diabetes, diarrhea, and other ailments in many countries. Guava belongs to phylum *Magnoliophyta*, class Magnoliopsida and Myrtaceae family (Dakappa *et al.,* 2013). It has about 133 genera and more than 3,800 species. *Psidium guajava* and all it's parts have an old history of medicinal value (Nwinyi *et al.,* 2008). The plant is well known by a common name "Guava" in English, guayabo in Spanish, goyaveandgoyavier in French, guyabaorgoeajaab in Dutch, goiaba and goaibeira in Portuguese and jambubatu in Malaya. Pichi, posh and enandi are the names commonly used in Mexico and America (Morton, 2004). Guava plant grows widely in the tropic areas because it is a plant that can be grown on a big range of soils (Jiminez-Escrig, 2001). In Mexico guava is one of very important crop which is cultivated over 36,447 acres and production is about 192,850 tons. According to records the first money-making guava planting was reputable around 1912 in Florida at Palma Sola (Morton, 2004). In this review we describe the botany, ecology and medicinal value of this useful plant.

General uses of Guava

The guava fruit contains vitamin A, C, iron, phosphorus and calcium. It has more vitamin C than the orange. The fruit contains saponin, oleanolic acid, lyxopyranoside, arabopyranoside, guaijavarin, quercetin and flavonoids. Ascorbic acid and citric acid are the major ingredients of guava that play important role in anti-mutagenic activity. The skin of fruit contains ascorbic acid in very high amount; however, it may be destroyed by heat. The strong pleasant smell of fruit is credited to the carbonyl compounds. Guava fruit contains terpenes, caryophyllene oxide and p-selinene in large quantity which produce relaxation effects. The flavonoid content is higher in the methanolic extract of the guava. There are 41 hydrocarbons 25 esters, 13 alcohols and 9 aromatic compounds in guava. Titratable acidity and the total soluble solids are present in fruit. Guajadial is also present in guava.

Essential oil is present in leaves which contain α-pinene, limonene, β-pinene, isopropyl alcohol, menthol, terpenyl acetate, caryophyllene, longicyclene and β-bisabolene. Oleanolic acid is also found in the guava leaves]. Leaves have high content of limonene about 42.1% and caryophyllene about 21.3%. Leaves of guava have a lot of volatile compounds.

The bark includes 12–30% of tannin and one source declares that it includes tannin 27.4%, or polyphenols, resin and the crystals of calcium oxalate. Tannin is also present in roots. Leukocyanidins, gallic acid and sterols are also present in roots. Carbohydrates with salts are present in abundance. Tannic acid is also its part.

If guava fruit is healthy, then its leaves are super healthy. Some of the benefits of guava leaves includes - it helps in stopping diarrhea, reduce cholesterol level, helps in losing weight, helps to manage blood sugar levels, helps to fights cancer, helps in good vision, used for healing acne and helps in improving your skin texture. Guava leaves can either be boiled in hot water and consumed or made tea using them. Either of these will benefit you in many ways.

Guava leaves for healthy hair

Hair fall is a result of an unhealthy scalp. Guava leaves can help stop hair fall and strengthen your scalp because of their anti-inflammatory, antimicrobial and antioxidant properties. It is also being used in scalp related problems and dandruff.

It is also rich in vitamin B & C that helps in nourishing and aids in hair growth. So if you have a guava tree in your garden, then don't pile up those leaves or burn it, instead make it a point to make a paste out of it and gently apply it on your scalp. This will fight hair fall and help strengthen your scalp.

Guava leaves tea

If green tea is considered healthy and ayurvedic, then guava leaf tea is even healthier and this can be consumed if you are having abdominal pain, watery stools etc. All you need to do is to add guava leaves to boiling water and boil for 20 minutes. Then strain the water and allow it to cool for 5 minutes. Make sure it is at least lukewarm when you are consuming it. Also, this must be consumed on an empty stomach and you may find instant relief once you've followed the steps carefully.

Guava fruit is rich in most essential nutrients. The fruit is packed with fiber, vitamins, and minerals. It may help in diabetes treatment, protect heart health, boost immunity, and improve digestive health.

Medicinal importance of Guava

Psidium guajava L. is consumed not only as food but also as folk medicine in subtropical areas all over the world due to its pharmacologic activities (Deguchi and Miyazaki, 2010). Guava is frequently employed in numerous parts of the world for the cure of a lot of sickness like diarrhea reducing fever, dysentery, gastroenteritis, hypertension, diabetes, caries, pain relief and wounds. The countries which have a long history of using medicinal plants are also using guava at big level like Mexico, Africa, Asia and Central America. With its medicinal uses it is also used as food and in the preparation of food products. It is also used in house construction and toys making. Guava contains high content of organic and inorganic compounds like secondary metabolites e.g. antioxidant, polyphenols, antiviral compounds and anti-inflammatory compounds. Guava has a lot of compounds which have anti cancerous activities. It has a higher number of vitamins and minerals. Phenolic compounds like flavonoids also find an important place in the guava. Lycopene and flavonoids are important antioxidants. They help in the cure of cancerous cells and help to prevent skin aging before time (Manikandan and Anand, 2016). Guava can affect the myocardium inotropism. Guava skin extract can control level of diabetes after 21 days' treatment (Rai *et al.,* 2010).

Medicinal uses of Guava parts

Leaves: The decoction or infusion of the leaves is used as febrifuge, antispasmodic and for rheumatism in India (Hernandez, 1971). The leaves are used in USA as an antibiotic in the form of poultice or decoction for wounds, ulcers and tooth ache (Heinrich, 1998; Leonti et al., 2001). Bronchitis, asthma attacks, cough, pulmonary diseases could be also treated with guava teas (Batick, 1984; Khan and Ahmad, 1985).

Fruits: Guava fruit is rich in most essential nutrients. The fruit is packed with fiber, vitamins, and minerals. It may help in diabetes treatment, protect heart health, boost immunity, and improve digestive health.

Bark: The bark in the form of decoction and poultice is used as an astringent in the treatment of ulcers wounds and diarrhea in Philippines while in Panama, Bolivia and Venezuela, the bark is used in treatment of dysentery and skin ailments. In the form of decoction and poultice, it is used to expel the placenta after childbirth and in infections of the skin, vaginal hemorrhage wounds, fever, dehydration and respiratory disturbances (Gutiérrez *et al.*, 2008).

Root: The root is used in West Africa as a decoction to relieve diarrhea, coughs, stomach ache, dysentery, toothaches, indigestion and constipation; while in Philippines, Fiji and South Africa, the roots are used in the form of decoction and poultice as an astringent in ulcers wounds and in treatment of diarrhea (Gutiérrez *et al.*, 2008).

Whole plant: In general, the whole plant or it shoots are used in the form of infusion, decoction and paste as skin tonic in Tahiti and Samoa and as analgesia in painful menstruation, miscarriages, uterine bleeding, premature labor and wounds (Gutiérrez *et al.*, 2008).

Medicinal Chemical Properties of Guava

Here are some medicinal chemical properties of guava leaves:

Antimicrobial activity

Guava has a high antimicrobial activity. Guava leaf's extract doses can reduce the amount of cough due to its anti-cough activity. Aqueous, chloroform and methanol extract of leaves can reduce the growth of different bacteria. Due to its anti-cough activity it is recommended in the condition of cough (Jaiarj, 1999).

Antidiarrheal activity

Diarrhea is one of most common and well recognized health problem and a global issue. It is very common even in developed countries. It is estimated that about 2.2 million people die annually by diarrhea; most of them, are children or infants.

Anti-inflammatory activity

Extract of guava in ethyl acetate can stop the germ infection and thymus production. It can act as anti-viral agent. It is used as anti-inflammatory agent for skin.

Antioxidant activity

Antioxidants are molecules which retard the oxidation process. The oxidation reactions may produce free radicals which damage the cells by starting various chain reactions. Free radicals which damage the cells cause cancer and many other diseases. Antioxidants terminate the free radicals and stop the chain reactions. Examples of antioxidants include beta-carotene, lycopene, vitamins C, E, and A and other substances. Oxidative reaction is one of most important destructive reaction. Free radical's damage is responsible for a lot of disorders in human like nervous disorders, inflammation, debates and viral infections. When drugs are metabolized in body the free radicals are produced. Sometimes the environmental changes and hormones become the reason of free radical production. These free radicals are responsible for all the oxidation reactions.

Guava contains high amount of antioxidants and anti-providing nutrients which are essential not only for life but also help to control the free radical activities. It also has a variety of phytochemicals which are beneficial for human health like diabetes, obesity and high blood pressure. There are two common methods by which antioxidants neutralize free radicals that is DPPH and FRAP assay. Extracts of guava in water and organic solvents have a large quantity of antioxidants which can stop the oxidation reaction. The concentration of these compounds become high with the increase in concentration. Pink guava also has a high antioxidant activity.

Guava is highly rich in antioxidants which are helpful in decreasing the incidences of degenerative diseases such as brain dysfunction, inflammation, heart disease, cancer, arteriosclerosis and arthritis. In fruits, the most abundant oxidants are polyphenols and ascorbic acid.

CONCLUSION

Guava is a traditional remedy for a number of ailments. Preliminary research suggests that compounds in guava leaf extract may have a positive effect on a range of illnesses and symptoms, including menstrual cramps, diarrhea, the flu, type 2 diabetes, and cancer. However, scientists need to carry out further studies in humans to confirm and better understand these findings. *Psidium guajava* (guava) is well known tropic tree grown in tropic areas for fruit. It is found to be effective in diarrhea, dysentery, gastroenteritis, hypertension, diabetes, caries, pain relief, cough, oral ulcers and to improve locomotors coordination and liver damage inflammation. The fruit is rich in vitamins (A & C), iron, phosphorus and calcium and minerals. The phenolic compounds in guava help to cure cancerous cells and prevent skin aging before time. The leaves contain many fungistatic and bacteriostatic agents and important oxidants. Its ethyl acetate extract contains quercetinwhich can stop the germ infection and thymus production. Guava possess anti-viral, anti-inflammatory and anti-oxidant activities which can be useful for the prevention and treatment of diseases.

ABSTRACT

Ginger (Zingiber officinale Roscoe) a spice crop is a member of the family zingiberaceae and sub family zinigeradeae. It is a monocotyledonous crop which produces rhizomes that serve as the ginger for commerce. Although the exact centre of origin is not known with certainty, it is believed to have originated from south East Asia and has been grown in India and China for centuries. Presently ginger is cultivated throughout the humid tropical areas of the world. Ginger is considered the most widely used spice globall. Ginger enters international markets in three primary forms; fresh (green) ginger, preserved ginger and dried ginger. The dried ginger has more commercial importance compared to preserved or fresh ginger. Ginger have so many health benefits, it is used in treating ailment such as such as arthritis, cramp, rheumatism, constipation, fever and infectious diseases. The economic part is the underground rhizome, which is pungent and aromatic and used for culinary purposes in ginger bread, biscuits, cookies, candy, jam, alcohol, cakes, puddings, ginger ale, curry powders, soft drinks, soups, prickles and a lot of other products. It is in view of the above the potentials of the plant are reviewed.

Key words: Ginger, health benefits, rhizome, dried, fresh

INTRODUCTION

Ginger (*Zingiber officinale* Roscoe) a spice crop is a member of the family *zingiberaceae* and subfamily *zinigeradeae.* It is a monocotyledonous crop which produces rhizomes that serve as the ginger for commerce. Although the exact centre of origin is not known with certainty, it is believed to have originated from south East Asia and has been grown in India and China for centuries. Presently ginger is cultivated throughout the humid tropical areas of the world. Ginger is considered the most widely used spice globally (FAO, 2008).

Uses

The economic part is the underground rhizome, which is pungent and aromatic and used for culinary purposes in ginger bread, biscuits, cookies, candy, jam, alcohol, cakes, puddings, ginger ale, curry powders, soft drinks, soups, prickles and a lot of other products (Nauman *et al*., 2010) Ginger enters international markets in three primary forms; fresh (green) ginger, preserved ginger and dried ginger. The dried ginger has more commercial importance compared to preserved or fresh ginger. Aromatic spices are prepared by harvesting and drying the mature rhizome while the fresh ginger, consumed as a vegetable, use for making Ginger juice etc is harvested when immature or mature (Modupeola *et al*., 2012) Dried ginger is used directly as a spice and also for the preparation of ginger oil and ginger oleoresin. It is also valued as a medicinal plant widely used throughout the world to address a wide range of human ailments such as arthritis, cramp, rheumatism, constipation, fever and infectious diseases (Ali *et al*., 2008)

Botany

Ginger is an erect perennial herb usually cultivated as an annual, whitish or off coloured in appearance and which is much appreciated throughout the world. The plant reaches a height of 3 to 4 feet, the leaves growing 6 to 12 inches long. It is extensively cultivated in the tropics (Kaushal *et al*., 2007)

Ginger Production in Nigeria

Ginger (*Zingiber officinale Rosc*) is one of the most important spices grown in Nigeria. It was traditionally grown in the Ginger savannah region of Kaduna, particularly in southern Kaduna (Areas like Kachia, Kubacha, Kafanchan, Kwoi and Zankwa), research however has shown that it can equally do well in the rain forest region. Among the crops predominantly cultivated. In Southern Kaduna is ginger and is one of the most economically beneficial crops in southern part of Kaduna state. Ginger is produced in states namely: Kaduna, Nasarawa, Benue, Niger and Gombe with Kaduna as the major producer. Ginger cultivation in Nigeria dates back to 1927 and it is believed to have Asian origin. Ginger was introduced to Africa and the Caribbean by the Colonial Masters; and it is now cultivated throughout the humid tropics Although Nigeria ranks first globally in terms of land area devoted to ginger cultivation (56.23% of the total), it ranks third in terms of quantity of ginger produced, accounting for 12.54%of global production According to Food and Agriculture Organization in 2018, Globally, ginger production was estimated at over 3.3 million metric tons with India; China; and Nigeria as the world leaders. Nigeria produces and export good quality ginger; that contains less fiber which is generally preferred by Western countries. Ginger production, processing and marketing are big businesses that guarantee high returns on investment (Meadows, 1998).

AGRICULTURAL PRACTICES

Source of Planting Material

Seed rhizomes should be carefully preserved free from pests and diseases which are collected from organically cultivated farms (most preferable) or any farm, Research institutes or trusted dealers should be used for planting.

Land Preparation/Planting

Proper land clearing, ploughing and harrowing is important in the cultivation of Ginger, as it encourages the proferation of ginger roots for maximum exploitation of soil nutrients and moisture. The seed rate varies from 1500-2500kg/ha, planting can be done using planting hoes as the rhizome setts which are cut into pieces weighing between 20-30g are placed in the soil and well covered, this is the minimum weight of ginger recommended for planting, although other researchers recommends something higher,115 – 230g.majority of farmers ensure that each of the rhizomes setts has at least 23 eye buds means they are aware of the implication of such in successful ginger production and might have gained this knowledge from practical (Nwaogu *et al* , 2014).

Varieties

Studies have shown that most farmers in Nigeria preferred the black ginger this is also known as Monkey fingers and the yellow ginger (elephant foot), the black ginger is more pungent than the yellow ginger, but yield slightly less.

Mulching

Mulching the ginger beds with green leaves enhances the germination of seed rhizomes and the addition of organic matter to the soil and also conserves moisture during the later part of the cropping seasons (NIHORT, 2014). The first mulching is to be done with green leaves at 10-12t/ha at the time of planting. It is to be repeated at 5t/ha at 3 months after planting. This helps to moderate the soil temperature which needs to be maintained at 28-32^{o}C during the first three months after planting for good rhizome growth. Mulching should be done up to a thickness of 5cm with long lasting mulch material (NIHORT, 2014)

Soil Fertility Management

Organic manure such as green manure, compost wood ash or farmyard manure should be applied to return the nutrient removed from the soil by the crops as well as to improve the water and nutrient holding capacity of the soil by the crops. The amount of fertilizer required for a particular crop depends on the initial fertility status of the soil; fertilizer is best applied by broadcasting in two applications 300kg of NPK 15:15:15 is recommended /ha of ginger, applied in split applications half at planting and half at 4-6 weeks after planting (Olasanta, 1994). Farmyard manure or compost at 5-6 t/ha may also be applied as a basal dose at planting. Organic fertilization is very important to agriculture as the constant use of synthetic fertilizers over the years poses threat to human lives, Optimum growth and yield of plants require nutrients, as deficiency in nutrients results in stunted crop growth and poor yield (Modupeola *et al., 2012)*

Weed Control

Uncontrolled weed growth in ginger plots or farm may reduce rhizome yield by up to 76% compared to weeded plots or farms. The critical period for weed removal in ginger is 8-16 weeks after planting. This means the crop should be free from serious weed competition during the period. Manual weeding is done 4-6 weeks after planting and subsequent roughing. Weed growth after 20 weeks of planting does not affect rhizome yield much (Paul *et al*.,1988)

Pest and Disease

Disease and pests of ginger are rare when ginger is grown in fertile soils. However, high relative humidity and low soil fertility predispose it to the attack of leaf spot disease which, at the advanced stage, may tear the leaves into shreds and finally lead to premature death of the plant. To prevent the disease, select fertile soil and apply balanced fertilizer, plant early and mulch adequately to prevent soil splash on the leaves. Other diseases like fusarium, yellow and soft rot are rare. There is hardly any known pest of economic importance of ginger, although, root knot nematode (*meloidogyne incognita*) is said to be a common pest of ginger (Tabin *et al*., 2015)

Harvesting and Yield

The crop is ready for harvest in about eight to ten months depending on the maturity of the variety. When fully matured, leaves turn yellow and starts to dry up gradually, clumps are lifted carefully with a spade or digging fork and rhizomes are separated from dried leaves, roots and adhering soil. The average yield of fresh ginger per hectare varies with varieties ranging from 15 to 25 tons (Elliot, 2008).

Storage of Ginger

After setting aside planting material for the next season, ginger rhizomes are split and dried soon after harvest. Small quantities of ginger can be stored in covered pits, or in baskets covered with saw dust. Large quantities can be best stored in heaps under the shade of the tree and covered with dry grass, or in well-ventilated huts. The rhizomes should be sorted periodically to remove rotten ones. Seed rhizomes can also be stored in pits dug in the ground under the shade of tree provided there is no chance for water to enter the pits (Paul *et al*., 1998)

THE USE OF NATURAL HERBS AMONG POULTRY FARMERS IN OKENE LOCAL GOVERNMENT AREA OF KOGI STATE, NIGERIA

[1*]Usman, K. and [2]Orogwu, D.C.

Department of Agricultural Extension and Management, Division of Agricultural Colleges, Ahmadu Bello University, Zaria – Kabba Campus

*Corresponding author's e-mail: usmankabir808@gmail.com

ABSTRACT

The study was conducted to examine the use of natural herbs among poultry farmers in okene local government area, of Kogi state Nigeria. 100 poultry farmers were randomly selected and Data were collected through well structured questionnaire and interview schedule. The data were analyzed using descriptive statistic and logit regression. The result revealed that the model age of the farmers is 41-50years, while the mean age is 39years. Majority (90%) of the farmers attended formal educational and engage in poultry farming on a small scale. The result further revealed that age, level of education, poultry experience, flock size and access to veterinary services had positive and significant influence on the use of natural herbs by poultry farmers to manage and prevent poultry diseases are indeed effective and reliable based on the farmers' perception. Support and encouragement on the use of natural herbs by poultry far mers' provision of credit facilities will go a long way in improving the use of natural herbs for poultry's diseases control among poultry farmers in the study area.

Key words: Natural Herbs, Diseases, Poultry farmers, Okene, Kogi

INTRODUCTION

Poultry industry in Nigeria occupies a prominent position as a major source of supply of animal protein to the citizens. Over the years, the growth of poultry industry has followed a pattern closely dictated by the economic fortunes of the country. (USDA, 2013) however over the years, a synthetic antibiotic has been the main stay of the industry in terms of disease prevention, treatment and growth promotion of the animals. Furthermore, antibiotic resistance (AR), which is defined as the ability of an organism to resist the killing effects of an antibiotic to which it was normally susceptible, has become an issue of global interest. Thus, using antibiotics in animals may raise the risk of transmitting drug resistant bacteria to humans either by direct infection or by transferring resistance genes from agriculture into human pathogens. This has made some poultry farmer or poultry industry to turn to the use of natural herbs for disease prevention and treatment. (Tulobaeu, 2016), therefore, this study aims to assess the use of natural herbs among poultry farmers in Okene local government Area of Kogi State with specific objective, describe the socio – economic characteristics of poultry farmers in the study area; assess the prevailing diseases in poultry production in the study; assess the extent of usage of natural herbs in the study area; determine the factors that influence the use of natural herbs in the study area; and examine the perception of farmers on the efficacy of natural herbs treatment of poultry diseases in the study area.

MATERIALS AND METHODS

This study was conducted in Okene Local Government Area of Kogi State. This study area is within the northern guinea savannah ecological zone of Nigeria. It lies between latitude $7^0 30^I$N - $7^0 30^I$N and longitude $6^0 10^I$E - $6^0 16^I$E of the equator with an area of 328km2 and a population of 320, 260 (NPC 2006). The area has two distinct seasons in a year, the wet and dry seasons. The wet season span between April to October, while the dry season is between the months of November to March. The area has an average maximum temperature of 31^0c, and an average minimum temperature of 24^0c with annual rainfall is usually between 1, 100mm and 1, 300mm. the main occupation is cotton weaving is traditional craft, others engage in pet trading such as yam, cassava, corn (maize) sorghum, beans, peanuts (Groundnuts) palm oil and kernels and cotton grown in the surrounding area by the Ebira people. Animal husbandry is also practice in the area.

Sampling technique and Sample Size

The following technique was used to draw sample of 100 respondents from the L.G.A. purposive sampling technique was used to select individual respondents and 10 villages, (10) were involved in Okene L.G.A for the study. The distribution of questionnaire in the study area was based on the available number of poultry farmers in each village.

Data Collection

The primary data was obtained through the use of well structured questionnaire and oral interview. Secondary information on the other hand was obtained from journals, articles, documents of the local government, book and internet.

Data Analysis

Data collected was analyzed using both descriptive and inferential statistics. Descriptive statistics such as frequency, percentage and means was used to achieve objectives (i), (ii), (iii), and (iv) whereas logit regression was used to achieve objective (iv) of the study.

Model Specifications

RESULTS AND DISCUSSION

Analysis of the socio-economic characteristics of the poultry farmers in the study area

Table 1 shows that the mean age of the farmers was 39years. 10% of the farmers did not have formal education while 90% of the farmers acquired various forms of education. This implies that the farmers are educated enough to know the different types of herbs for various poultry diseases, their usage efficacy and implications. 90% of the farmers practice small scale farming with average flock size of 240 birds. 50% of the respondents have between 6-10 household sizes with a mean of 7%. This implies that farm operations in the study area will depend mainly on family labour particularly with me moderate flock.

Prevailing poultry disease in the study area

Ten (10) poultry diseases were reported by the respondents to be prevalent in the study area (Table 2). The commonest ones in order of prevalence include coccidiosis (100%), fowl cholera (90%), Newcastle disease (82%), fowl pox (81%), Gumboro (73%) and CRD (57%). Similar observations were reported by Atteh (2004), Mishra et al. (2010) and Lawal and Oyegbami (2010) that coccidiosis, fowl cholera, Newcastle disease, Fowl pox, Gumboro and CRD were responsible for over 71% of the total cause of mortality in poultry farming.

Extent of usage of Natural Herbs for various poultry disease

Table 3 shows that most of the poultry farmers use natural herbs mostly for coccidiosis (93%) fowl cholera (88%), Newcastle disease (80%), fowl pox (76%), Gumboro (64%) and CRD (51%). All the poultry farmers interviewed used plants natural herbs to treat poultry diseases. Farmers used these plants because they are readily available and at low or no cost at all. Locally available, easily accessible and culturally appropriate and are therefore readily understood. It is believed that natural herbs (traditional drugs) do not produce side effect.

Determinants of the use of Natural herbs by poultry farmers in the study area

Age, level of education, poultry farming experience, flock size and access to veterinary services had positive and significant influence on the use natural herbs by poultry farmers (Table 4). This implies that a unit increase in any of these socio-economic variables will lead to a unit increase in the use of herbal medicine to treat diseases in poultry farming in the study area. Furthermore, cox and snell R square of 0.49 indicate that 49% of the various in the use of herbal medicine in poultry production were influenced by the socio-economic characteristics of the farmers.

Farmers perception of the Effectiveness of natural herbs in poultry farming.

The use of local methods of managing and preventing poultry diseases are indeed effective and reliable or dependable (Table 5). The farmers generally preferred and had more confidence in their local methods because the materials needed are readily available, affordable and easy to employ.

Table 5: Farmers' perception of the effectiveness of natural Herbs in poultry farming

Perception	Frequency	%
Highly Effective	59	59
Effective	30	30
Undecided	5	5

Highly ineffective	1	1

CONCLUSIONS

From the findings of this study, poultry farmers in the study area use different natural herbs medicine to prevent or treat various poultry diseases ranging from coccidiosis, fowl cholera, Newcastle disease, fowl pox, Gumboro, CRD, etc with high level of effectiveness.

RECOMMENDATIONS

i. The following recommendation were made: the veterinary doctors and extension agents should support and encourage the use of natural herbs medicine among poultry farmers

ISSN: 2814-0508

ii. The local government should support by granting loans to the poultry farmers, to enable them expand their production capacity.

ABSTRACT

Studies on the use of alternative medicine in Nigeria are on the rise and this could be the antidote to reducing the country's rate of incidences of terminal diseases among both the young and the old. The present study investigated the various medicinal use of mustard seed among households in South-West Nigeria. The study ascertained the socio-economic characteristics of households using mustard seeds, determined the level of awareness and usage of mustard seed among respondents, ascertained the frequency of use of mustard seed among respondents in South-West Nigeria; and determine to perception of respondents on mustard seed in the study area. The study was carried out in South-West, Nigeria and sixty-four households were purposively from Lagos, Ogun and Ondo State.

Key words: Mustard Seed, Alternative medicine, South West, Nigeria.

INTRODUCTION:

Mustard is the common name for several herbaceous plants in the genera *Brassica* and *Sinapis* of the Brassicaceae family, and in particular *Sinapishirta* or *Sinapis alba* (white or yellow mustard; sometimes classified in *Brassica*), *Brassica juncea* (brown or Indian mustard), and *Brassica nigra* (black mustard), all three of which produce small mustard seeds that can be used as a spice and, by grinding and mixing them with water, vinegar, or other liquids, be turned into a condiment also known as mustard. The seeds are also pressed to make mustard oil, and the edible leaves can be eaten as mustard greens. Mustard has been called the third most important spice after salt and pepper (Downey, 2003). Mustard seeds are very rich in phytonutrients, minerals, and anti-oxidants, and are an excellent source of essential B-complex vitamins such as folates, niacin, thiamin, riboflavin, pyridoxine (vitaminB-6), and pantothenic acid. These B-complex groups of vitamins help in enzyme synthesis, nervous system function and regulating body metabolism. Mustard seeds contain flavonoid and carotenoid antioxidants such as carotenes, zeaxanthin, and lutein. In addition, the seeds contain a small amount of vitamin antioxidants such as vitamin-A, C, and Vitamin-K. Mustards are rich source of health benefiting minerals. Calcium, manganese, copper, iron, selenium and zinc are some of the minerals especially concentrated in these seeds.

MATERIALS AND METHODS

The study was carried out in South-West, Nigeria. A multi stage sampling technique was used to select three states in South west; these are Ondo, Ogun and Lagos State. A purposive sampling technique was used to select areas where mustard seed is commonly used. Twenty-one households were selected from Lagos and Ogun State while twenty-two house-holds were sampled in Ondo State. These makes a total of sixty-four household sampled for the study. Data were obtained with the aid of a simple structured questionnaire which had been previously validated by experts in the field of extension. The reliability of the questionnaire was 70.5 %. Data were subjected to descriptive and inferential statistics

RESULTS AND DISCUSSION

Socio economic characteristics of respondents

Table 1 revealed that the mean age of the respondents is 41.2 This implies that majority of the respondents in the study area are within the middle age category and have the ability to try out relatively new innovations or practices. More than half (53.8%) of the respondents had between 1-6 years of formal education. 66.2% of the respondents are likewise married. This could imply that their marital status could aid or reduce the usage of mustard seed as decision taken by individuals to use or not use mustard seed could be influenced by family or spouse's preferences. 44.1% of the respondents are Christians and Muslims alike hence, there is no disparity of religion in the use of mustard this negates the a priori expectation that Christians will likely use mustard seed more than any other religion. The mean income of respondents is ₦27,986 monthly as majority (42.1%) and (34.5%) of the respondents are artisans and civil servant respectively which could be as a result of the new minimum wage salary scale. Concussively respondents in the study area could afford to purchase mustard seeds for use.

Table 1: Socio-Economic characteristics of Respondents (N=145)

Socioeconomic characteristics	Frequency (%)	Mean Score
Age		
<31	37 (25.5)	
31-50	72 (49.7)	
51-70	31 (21.4)	41.2
>70	5 (3.4)

Awareness of mustard seed

Table 2 shows that majority (88.3%) is aware of mustard seed and 26.9% of the respondents with source of awareness from their place of worship. It can be deduced from the results that respondents in the study area are aware of mustard seed. This is further expected to have positive influence on its use.

Table 2: Respondents Awareness of Mustard Seed (N=145)

	Frequency (%)
Awareness of Mustard Seed	
Yes	128 (88.3)
No	17 (11.7)

Use of mustard seed among respondents

Table 3 shows that 61.4% of the respondents used mustard seeds. However, there were variations in frequency of use as 22.5% of the respondents used mustard seed on daily basis, 46.1% used it on weekly basis, while 31.4 used mustard seed monthly. With respect to the type of mustard used, the brown type was prominent as 48.3% of the respondents indicated its use. Other types of mustard seeds used by the respondents include: black (31.5%) and yellow type (20.2%). The major forms of use were raw and powdery form, with most (55.1%) indicating preference for raw form, while 44.9% preferred it in powdery/blended form.

Table 3: Respondents Usage of Mustard Seed (N=145)

	Frequency (%)	Rank
Usage of Mustard Seed		
Yes	89 (61.4)	
No	56(38.6)

Constraints to use of mustard seed

Result in Table 4 revealed the constraints militating against the use of mustard seed. Cost (41.4%) and Non determinant of dosage (31.0) ranked first and second, respectively. The cost of mustard seed being a constraint could be associated with its low level of production in Nigeria which invariably influences its market price in. Other constraints to use of mustard seeds are: Its non-availability (13.1%) and fear of getting original seed (2.1%), while inadequate information on its usefulness ranked least constraint to use of mustard seed.

Table 4: Respondents Constraint to usage of Mustard Seed (N=145)

Constraints	Not constraint	Mild constraint	Serious constraint
Non availability/scarcity	95(65.5)	31(21.4)	19(13.1)
It is expensive	53(36.6)	32(22.1)	60(41.4)
Scarcity	87(60.0)	55(37.9)	3(2.1)
Inadequate information on its usefulness	116(80.0)	29(20.0)	0(0.0)
Non determinants of dosage			
Fear of getting original seed	69(47.6)	31(21.4)	45(31.0)
	59(40.7)	55(37.9)	3 (2.1)

Trado-medicinal use of mustard seed

According to Sri Wahjuni *et.al* (2019), the use of traditional medicine is considered to be 'safer' than using synthetic drugs. Experience also proves that not all synthetic drugs are able to overcome various health problems optimally. Data on Table 5 reveals several illnesses that mustard seed cured. More than half (61.8%) of the respondents attested to the effectiveness of mustard in regulating blood sugar, 59.6% and 53.1% of the respondents opined that it was effective in treating arthritis and body pain, respectively. This is in consonance with the finding of Yadav and Kumari (2013) who opined that the linoleic acid found in mustard seed have been proven to be effective in treatment for rheumatism and arthritis. Other ailments that could be treated with mustard seed as identified the respondents were headache (50.0%), stomach ache (50.0%) and menstrual pain cramp (47.6%).

Table 5: Percentage of distribution of trado-medicinal use of mustard seed

Diseases/ sickness	Freq.	%
Regulation of blood sugar	37	61.4
Infertility	30	31.0
Menstrual pain and cramp	29	47.6
Arthritis	19	59.6
Ulcer	25	42.1
Body pain	32	53.1
Malaria	24	39.3
Headache	30	50.0
Cough	24	39.3
Stomach ache	36	50.0
Eye problem	19	31.0
Migraine	25	42.1
Fibroid	23	37.6
Insomnia	17	28.7

Source: Field Survey (2020)

CONCLUSION

The study found that respondents in the study area were young, educated and low income earners. The study also established a high level of awareness of mustard seed among respondents. The study also found variations in usage ranging from daily, weekly and yearly. The study revealed that several illness ranging from low blood sugar, arthritis and body pain, headache stomach ache and menstrual pain cramp were treated with mustard seed. Despite the benefits accrued from its use, certain factors such as non-availability or scarcity of mustard seed and cost were major constraints to use of mustard seed

ABSTRACT

The study focuses on the ethno botanical uses of Moringa oleifera in Kaugama Local Government Area of Jigawa State, Nigeria. Well-developed structural questionnaires (100) were randomly administered on respondents from five (5) selected villages which include; Viz Yalleman (east), Turmi (north)Hadin (south), Marke (west) and Kaugama main town (Kofar arewa, Fada and B/Kasuwa). Data collected were analyzed using simple descriptive statistic. The study revealed that majority of the respondents were female (80%), while male was made up of 20%. Most of the respondents involved in Moringa oleifera cultivation were above 40 years old (70%). Hence, Government should assist in improving the cultivation of Moringa oleifera in a mechanized way.

Key words: Ethno botanical, Quality, Jigawa State, *Moringa oleifera*, medicinal uses

INTRODUCTION

Moringa (*Moringa oleifera* Lam) is the most widely cultivated species of the monogenetic family "Moringaieae" (Order: Brassicals) that includes 13 species of trees and shrubs distributed in sub Himalayan range of India, Sri Lanka, north eastern and south western Africa (Fahey, 2005). Today it has become localized in many locations in the tropics and is widely cultivated throughout African countries as well as Burma, Singapore, Mexico and Malaysia (Fahey 2005). Moringa species is one of the world's most useful plants and is a fast growing tree cultivated throughout the tropics for human food, livestock forage, medicine, and dying and water purification. The tree is known by several names in different countries, but is most popularly called the "drum sticks tree" for its pods that are popularly used by drummers and the: horse radish tree" for the flavor of its roots (Palada and Chang, 2003). Moringa is one of the world's most nutritious crops. Ounce for ounce, the leaves of—Moringa have more beta-carotene than carrots, more protein than peas. More vitamin C than orange, more calcium than milk, more potassium than banana, and more Iron than spinach. This tree is becoming a vital source of nutrition in this region, where most of the world's poor people live. The multiple uses of Moringa have attracted the attention of many people in the world today (Palada and Chang, 2003). The tree can be found growing naturally at elevations of up to 100m above sea level. It can grow well on hill sides but is more frequently found growing on pastureland or in river basins. It is a fast growing tree and has been found to grow 6-7m in one year in areas receiving less than 4000mm mean annual rainfall (Odee, 1998). *Moringa oleifera* is an important and miraculous tree. The relative ease with which it is propagated through both sexual and asexual means and its low demand for soil nutrients and water after being planted makes its production and management easy. Introduction of this plant into farms with bio dense environment can be beneficial for both the owner of the farm and the surrounding eco-system (Foidi et al., 2001).

MATERIALS AND METHODS

Description of the Study Area

The study was conducted in Kaugama Local Government area of Jigawa State, Nigeria. Kaugama is a Local Government Area in the north of Jigawa State, Nigeria. Its headquarters are in the town of Kaugama. It has an area of 883 km^2 and a population of 127,956.

Data Collection

A total of 100 questionnaires were randomly administered to some selected villages: Yalleman (east), Turmi (north), Hadin (south), Marke (west) and Kaugama main (K/Arewa, Fada, B/Kasuwa). All the questionnaires were returned successfully.

Data Analysis

The data obtained was subjected to simple descriptive statistics such as percentages and frequency distribution

RESULTS AND DISCUSSION

Table 1 indicates that females are more engaged in *Moringa oleifera* activities in the study area. Female has the highest value (80%) followed by male with (20%). Similar finding was obtained by Palada and Chang (2003). Table 2 shows that 10% of respondents are within the range of 15-25 years old, while 70% are above 46 years old. Majority of the respondents are married (55%), while 40% widowed in the study area (Table 3).

Table 1: Sex

Table 4 indicates how the people obtain *Moringa oleifera* plants. It was discovered that 35% of the people obtained if by cultivation, 65% by purchasing, while none obtained from the forest. From all indications, people get *Moringa oleifera* from purchasing. The study revealed that 50% of the respondents in the study area uses *Moringa oleifera* for food, while 20% use it for medicine, and 28% for water purification (Table 5). This means that *Moringa oleifera* plants are widely used for both consumption and non-consumption purposes. This indicate that *Moringa oleifera* is widely acceptable and highly utilized in the northern parts of the country.

Table 4: Method of obtaining

Fence	1	I
Water purification	28	28
TOTAL	100	100.

Source: Field survey 2021.

In Table 6, it was observed that 85% of the respondents highly utilized leaves as a source of food leaves, while 15% uses fruit/pod. This means that the respondents in the study area use fruit/pod for water purification to substitute alum. This agrees with similar finding of Fahey (2005). Table 7

ISSN: 2814-0508

indicates parts of *Moringa oleifera* plants mostly used as medicine by man. It was discovered that the leaves had the highest percentage with 35%, Bark 10%, Seed 2%, Root 25%, while fruit had at least 28% due to the water purification to substitute alum.

Table 6: Perception of *Moringa oleifera* as sources of food

CONCLUSION

In conclusion, *Moringa oleifera* (Linn) is used for food, medicine, fuel wood, water purification and curing some diseases in Kaugama Local Government Area, Jigawa State, Nigeria

RECOMMENDATIONS

Based on the finding of the study, the following recommendations are to be considered by the Government and non-governmental organizations:

- Provision of improved seedlings to the farmers,
- Encouragement of the farmers through provision of loans for enhanced production of *Moringa oleifera* production,
- Training of farmers in the study area on Good Agricultural Practices involved in *Moringa oleifera* production.
- Mechanization cultivation of *Moringa oleifera*.

ABSTRACT

This study represents an attempt to document information on the common medicinal plants used in Nigeria. These plants can be used as remedies for different aliments in our homes. The study identified 325 species and 95 families of plants being used by most of the people in Nigeria for the treatment of various common diseases. The medicinal uses are varied and the plant parts that are used ranged from leaves, roots, stem, bark to fruits only, or a combination of two or more in a species or with those of other species. Enduring and sustainable conservation efforts should be made to safeguard these important medicinal plants by processing and packaging it so that it can be stored and sold without losing its efficacy.

Key words: Medicinal plants, Herbs, Package, Utilization Storage

INTRODUCTION

Herb plants constitute an effective source of both traditional and modern medicine. These plants have been shown to have genuine utility and about 80% of the rural population depends on them as primary health care (Akinyemi, 2000). Herb plants have been used as sources of remedies for the treatment of many diseases since ancient times and people of all countries of the world including Nigeria have this old tradition. Despite the remarkable progress in synthetic organic medicinal products of the twentieth century, over 25% of prescribed medicines in industrialized countries are derived directly or indirectly from plants (Newman *et al.,* 2000). Up to 80% of the Nigeria population uses medicinal plants as remedies (Hostellmann and Marston, 2002).

According to the World Health Organization (WHO), the definition of traditional medicine may be summarized as the sum total of all the knowledge and practical, whether explicable or not, used in the diagnosis, prevention and elimination of physical, mental or social imbalance and relying exclusively on practical experience and observation handed down from generation to generation, whether verbally or in writing. In Africa, traditional medicine made use herbs from plants and this plays an important role in the health of millions of people. Traditional medicine has been described by the WHO as one of the surest means to achieve total health care coverage of the world's population. Of the 2, 500,000 higher plant species on earth, more than 80,000 are medicinal. India is one of the world's 12 biodiversity centres with the presence of over 45000 different plant species. The use of traditional medicine in various therapies by the indigenous population over the world cannot be overemphasized, according to the World Health Organization (WHO), as many as 80% of the world's people depend on traditional medicine for their primary healthcare needs. Due to poverty, ignorance and unavailability of modern health facilities, most people especially rural people are still practice traditional medicines for their common day ailments. (Khan, 2002).

There is increase in the use herbal plants among the present generation of people because of benefits of derived from the use. (Cox, 2005). The older generation is showing more interest in this valuable science of healing although the youths are not left out. All over the world, several ethnobotanical studies focusing on medicinal plants have been documented (Singh and Singh, 2001; Wang et al., 2002; Cox, 2005; Kumar et al., 2005; Pei, 2005). In Nigeria, information about ethnobotanical studies has also been documented (Gill, 1992; Sofowora, 1993; Igoli et al., 1999: El-Ghani, 2016). Studies have shown that 325 species and 95 families of medicinal plants were recognized as being used by most of the people in Nigeria for the treatment of various common diseases. Fabaceae has the largest number of species (42), followed by Asteraceae (22), Euphorbiaceae (20), Acanthaceae (13) and Apocynaceae (12). The largest genera were Euphorbia (6 species), Cola and Hibiscus (5 species for each), Albizia, Acacia, Combretum and Ficus (4 species for each), Acalypha, Allium, Clerodendrum and Cleome (3 species for each).

Studies also revealed that traditional medicinal practices have a wide acceptability among the Nigerian people, probably because they believe in its effectiveness. The medicinal uses are varied and the plant parts that are used ranged from leaves, roots, stem, bark to fruits only, or a combination of two or more in a species or with those of other species.

This paper presents common medicinal plants used for local herbs and how to package them using modern ways. This documentation of medicinal uses of African plants is becoming increasingly urgent because of the rapid loss of the natural habitat for some of these plants due to anthropogenic activities. The following are the common medicinal plant used for local herbs:

Moringa: Moringa is energy booster, strengthens immune system, and has antibiotic properties, cures headaches, asthma, reduces arthritic pains and inflammations and restrict tumor growth.

Aloe vera: It has an amazing properly of water retention in its leaves that help in certain conditions such as constipation, and poor body immunity.

Ginger: It plays a vital role in digestion and also helps in controlling blood pressure. It also helps during menstruation.

Mint: It keeps the digestive system running and boost immunity. It also helps in keeping the mosquitoes away.

Spinach: It has riboflavin and beta carotene that improve cardiovascular and nervous system.

Partminger (Cury leaf, Efirin): It is used in soup making and salad. The leaves are widely believed to aid digestion. The crushed leaf paste can stop nose bleeding.

Lemon grass (Kooko-oba): It is easily cultivated and made into herbal tea and making pepper soup. It is used to relieve thrush (yeast infection) and an ingredient in black soap and body cleanser.

Roselle: There are two flowering varieties, the red and the white. The white flower is used for making soup and the red flowers are used for making hibiscus tea usually called "zobo". It lowers blood pressure and cholesterol. It destroys cancer cell.

Bitter leaf (Ewuro): Many Nigerians uses it as medicinal component of their diets. It is bitter, as name implies, but this can be reduced by crushing it and washing the leaves and boiling before the leaves are cooked as bitter leaf soup or added as garnish to enhance the flavour of stew. Traditionally, it is used to treat fever, malaria, hepatitis, diarrhea, dysentery and cough. It is rich in vitamin and mineral that helps to reduce blood sugar drastically, repairs the pancreas and kidney.

Bitter Kola: The fruit, when added to other herb/vegetable, helps to remedy many aliments in our body.

***Adensonia digitata* (luru):** The powered leaves are very high in vitamin, calcium, phosphorus, potassium protein and lipids. It is antimalaria, antiviral, anti-oxidant and anti-inflammatory.

***Iruingia gabonesis* (Bush Mango Ogbono):** It is used for making soup that helps persons with over weight, reduce abdominal fat, lower cholesterol and reduce chance of developing heart disease, cancer, stroke, kidney failure and high blood pressure.

***Garcinia kola* (Orogbo):** It has analgesic /anti-inflammatory effect. It prevents glaucoma.

Different types of packing herb plants

The plant parts that are used as herb are principally the roots, leaves and stems. These plant parts of the herb should the identified, removed and processed. The processing involves, removal of dirt by washing, drying and sorting. Drying should be done at room temperature or electric oven. The processed parts can be package in the following ways.

1. **Nylon:** Rhizome, root, tuber and leaves can be packaged in transparent nylon.
2. **Bottle:** liquid or powder herbs can be packaged in sealed bottles.
3. **Plastic Container:** The seeds or fruits can be stored in transparent container with cover,
4. **Paper container**: can also be used for powder herb and fruits
5. **Capsulated: T**his is quite expensive

Safety and efficacy of packaged herb

Safety and efficacy depends upon storage, packaging and handling of raw material, quality control during the process of production of herbal medicine, and their self life time, preservative used and pesticide residue etc. For all these reasons, it is evident that the raw herbal requires a series of extended studies aimed at establishing the safety and efficacy of raw herbal by changing or improving the methods of storage and handling of raw herbs used. Exposure to light, oxygen and microbes have direct effect on the shelf life of the herbs. Air oxidizes the raw herbs whereas light decomposes the herbs as a result of which stability is reduced. Raw herbs need to be carefully studied to select suitable packaging material so that products are compatible with the material and retain properties. Herbals may be stored under conditions that prevent contamination and deterioration. The effects of atmosphere, moisture, heat and light should be taken into consideration so that the active constituent of herbs remains stable for a longer period of time. Changes in colour, odour and taste physical structure are the indications for the deterioration of medicinal constituents of the herbs. Contamination and deterioration can be prevented by proper storage methods which ensure the safety and efficacy of finished herbal products. Before the storage of herbs, they must be cleaned, washed in order to remove earthy material and other contaminants and dried properly.

Steps involved for proper storage of herbs

· Identification by naked eyes

· Washing of herb parts- Washing of herb parts like stem barks, roots, leaves, stems may be done with potable water.

· Drying of herb parts

· Removal of microbes from herb parts

Sterilization of herb parts

Sterilization of herb parts, which needs to be stored, may be done by any of the methods below as applicable:

· Dry heat sterilization,

· Steam sterilization,

· Sterilization by radiation like infra-red radiation, UV rays, X-rays and Gama rays, Alpha radiations and Beta radiation.

· Chemical method – Gaseous sterilization like ethylene oxide.

Temperature for storage of herb parts

All the herb parts may be stored at a cool place (any temperature) between 8^0 - 25^0C. Herb parts must be protected from moisture, freezing, light and excessive heat for preventing decomposition. There are no guidelines for proper storage of herb parts till date. It is only the proper handling, packaging and storage of herb parts which can preserve the safety, efficacy and quality of herbs. Exposures to air, moisture, light, dust etc. are harmful and should be restricted to maximum extent.

Each lot of herbs packaged should bear a label with following details: Name of herb, part (root, stem, bark, leaf, flower, rhizome etc), Inspection status (tested/rejected/approved), date of arrival and consignment number, test report number and date, time of collection, best use before date, batch no., and geographical region of collection.

CONCLUSION

Herbs may be stored under controlled temperature, pressure, air and light etc in order to retain the active constituents of the herbs in different stores with proper labeling after packaging with specific packing material for different parts of the medicinal herbs. In this way, safety, efficacy and quality of the herb shall be maintained.

ASSESSMENT OF NUTRIENT COMPOSITION AND PHYTOCHEMICALS IN EXTINCT INDIGENOUS LEAFY VEGETABLES OF SOUTHWESTERN, NIGERIA

[1]Adegbola, R.A. and [2]Ademoyegun, O.T.

[1]The Polytechnic, Ibadan, Chemistry Department, PMB 022, UIPO, Ibadan, Nigeria

[2]National Horticultural Research Institute, PMB 5432, Idi-Ishin, Jericho, Ibadan, Nigeria

ABSTRACT

Southern Nigeria is blessed with diverse indigenous leafy vegetables that are rich in nutrients and phytochemical which are going into extinction from our diets because of lack of literature on their usefulness. The present research assesses phytochemicals, vitamins, minerals, proximate, beta carotene and chlorophyll in eight leafy vegetables namely: Yanrin (Launea taraxacifolia), Gboro (Solanum notrifolium), Gbagba (Solanium aethiopicum), Oguma (Solanum Scabrum), Odu (Solanium americanum), Morogbo (Sesamum radiatum), Efinrin (Ocium gratissimum), Curry (Colocasia rotis). Recommended procedures were used in the analyses. Phytochemical analysis showed all eight vegetables contained flavonoids, tannis and alkaloids while all except Solanum scabrum and Ocium gratissimum did not contain saponin. Vitamin C content ranged between 23.25±0.75mg/100g and 14.14±0.69mg/100g, Vitamin B_1 0.149±0.003 and 0.06±0.008ma/100g; Vitamin B_6 0.7425±0.0005 and 0.315mg/100g. Mineral analysis revealed high level of calcium and potassium 282.2 to 71.0mg/100g and 920.0 to 450mg/100g respectively, magnesium was between 122.0 and 19.79ma/100g, sodium 66.64 and 10.0mg/100g and iron 10.1 and 0.85mg/100g. Beta-carotene content showed 258.49±3.86 and 96.45±3.86µg/100g while chlorophyll a was 31.51±0.02mg/g tissue and 5.23 ±0.20mg/g tissue and chlorophyll b was 28.65±0.06mg/g tissue and 4.72±0.20mg/g tissue. The results revealed that eight leafy vegetables are good sources of nutrients and phytochemical that can be used to cure or prevent some diseases.

Key words: Nutrient Composition, Phytochemical, Beta-carotene, Chlorophyll

INTRODUCTION

Nature provides us with diverse fruits and vegetables that are used for food and healing (Kimura and Rodriguez-Amaya, 2003; Znidarcic *et al.,* 2011). In Southwestern Nigeria some of the vegetables that are used as food by earlier settlers are now termed as weeds and are no more part of our diet despite the health benefit that are in these vegetables. There are wide varieties of indigenous fruits and vegetables found in Africa, which are good sources of nutrients, vitamins, antioxidants, minerals and proteins (Odhav *et al.,* 2007). Some of these fruits and vegetables are mainly used by inhabitants for medicinal purposes (Eifediyi *et al*., 2008). A vegetable is any edible plant or its parts, intended for cooking or eating raw. Leafy vegetables constitute important functional food components by contributing vitamins, minerals and biologically active compounds which are associated with dietary activities

Plants make an amazing variety of plant pigment molecules which may have physiological or biological functions (Brian, 1997). Three types of pigments present during the aging of leaves are chlorophyll, carotenoids and anthocyanins. These food pigment in the leafy vegetables are sources of powerful antioxidants; which helps body scavenge free radicals, thereby limiting the damage to cell membrane DNA and protein structures in the cell (Druesne-Pecollo *et al*., 2010). Leafy vegetables contained essential macro minerals and micro minerals. The amounts required in the body are not an indication of their importance. Some of the functions these elements are helps muscles to relax and contrast, proper fluid balance, and nerve transmission and muscle contraction.

In-sufficient research in the overall assessment of the nutritive and health benefits of leafy vegetables presently studied may be a major cause of them going into extinction. Therefore, the present study assessed the nutrient composition and phytochemical in extinction indigenous leafy vegetables of southwest, Nigeria.

MATERIALS AND METHODS

Samples of eight indigenous leafy vegetables were collected on a single day at the Botanical garden, The Polytechnic, Ibadan: *Yanrin (Launea taraxacifolia), Gboro (Solanum notrifolium), Gbagba (Solanium aethiopicum), Oguma (Solanum Scabrum), Odu (Solanium americanum), Morogbo (Sesamum radiatum), Efinrin (Occium gratissimum)* and Curry *(Colocasia rotis)* between 7:30am and 8:30am. Location was to ensure the vegetables were exposed to the same condition. After collection, 100g of each vegetable was weighed, stored in transparent plastic bags, covered with aluminum foil, identified at Nigerian Horticultural Centre (NIHORT), Ibadan, Oyo State, Nigeria and taken to the laboratory. The vegetables were washed under running water, dried on paper towels, cut into small pieces, and homogenized for subsequent trituration. Extraction of beta-carotene, chlorophyll and digestion of minerals from the vegetable was performed on the same day of collection. Proximate composition and water soluble vitamins were determined. Phytochemical screening of crude extract was carried out using standard procedures. The method by AOAC 2005 was used for mineral analysis, beta-carotene, chlorophyll, proximate composition and water soluble vitamins. Minerals were determined by Atomic Absorption Spectrophotometer (model 400 Perkin Elmer Analyst), Flame Photometer for the analysis of sodium and potassium and Sp 30 UV visible Spectrophotometer (Pye Unicam, Cambridge) for the analysis of beta-carotene and chlorophyll.

RESULTS

Results of the analysis were presented in figures below:

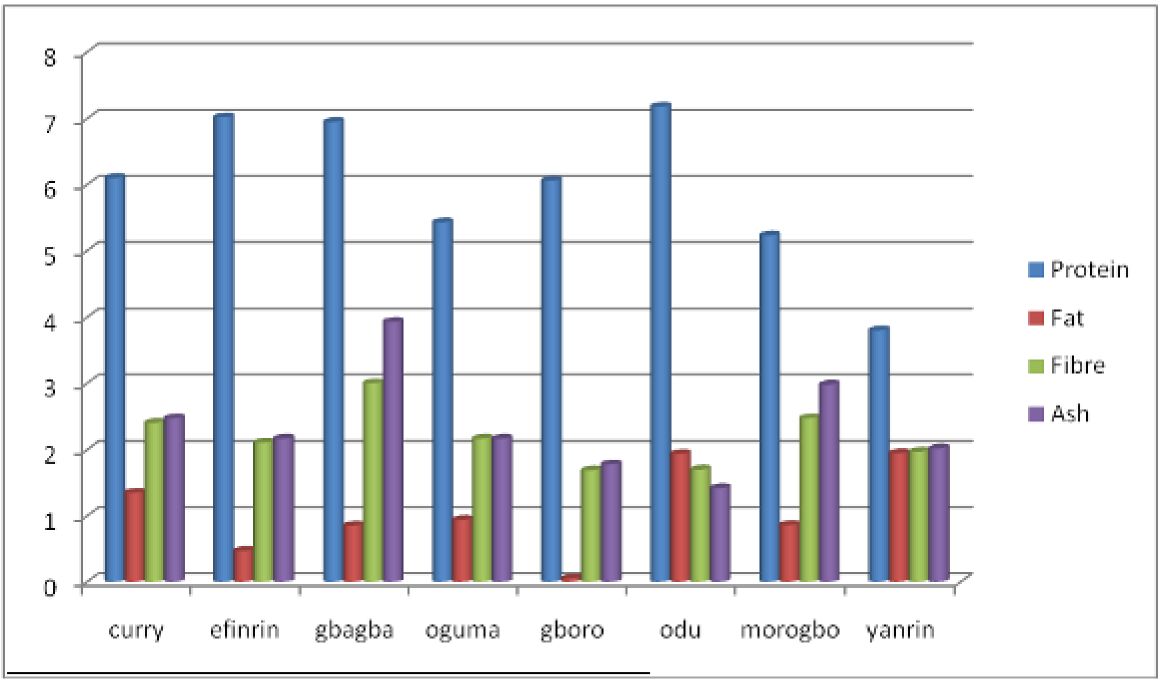

Figure 1: Proximate analysis of eight leafy vegetables in percentage (%)

Moisture content of eight leafy vegetables ranged between 84±1.00 and 78.0±1.00 curry had highest content and *oguma* least, this was not captured in the figure as it will affect the visibility of other parameter. *Odu*, *efinrin* and *gbagba* showed highest protein content while *yanrin* had least content. *Yanrin* and *odu* showed highest fat content and *gboro* had least content. *Gbagba* and *morogbo* had highest content of fibre while *odu* and *gboro* were lowest. *Gbagba* had highest ash content and *odu* lowest (Fig. 1).

The eight samples analysed produced β-carotene of mean 184 and 98 for OCC and AOAC respectively. The β-carotene in OCC and AOAC, with SD of 61 and 28, respectively (Fig. 2, 3).

Eight samples used in the two instruments produced total carotene of mean 15.98 and 15.36 for OCC and AOAC respectively. The mean of total carotene in OCC is slightly higher than AOAC, with the p-value of 0.0894 there is no statistically significant different between Open Column Chromatography and AOAC methods in analysing chlorophyll content. Therefore, the Open Column method of analysis is better than AOAC method (Fig. 4).

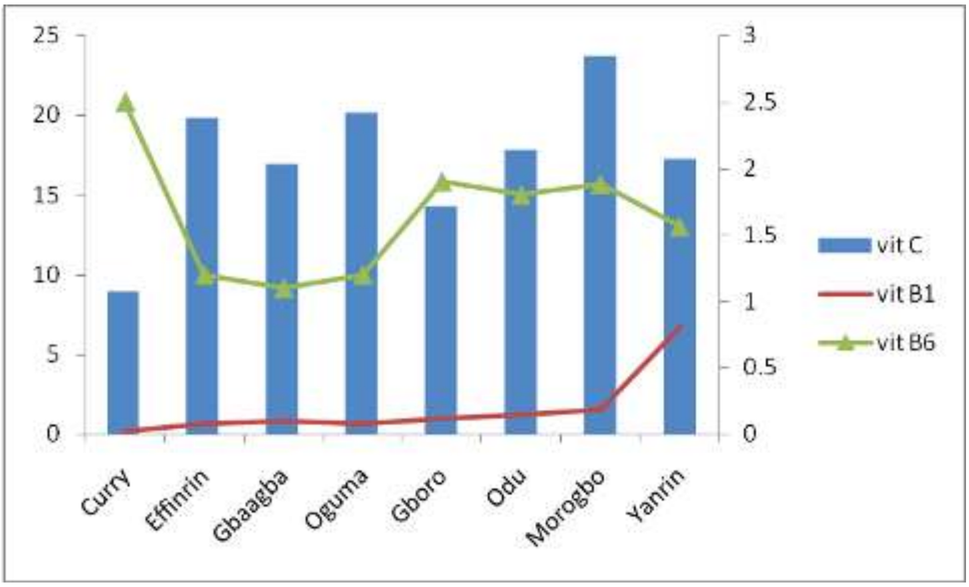

Figure 2: Water soluble vitamins in mg/100g

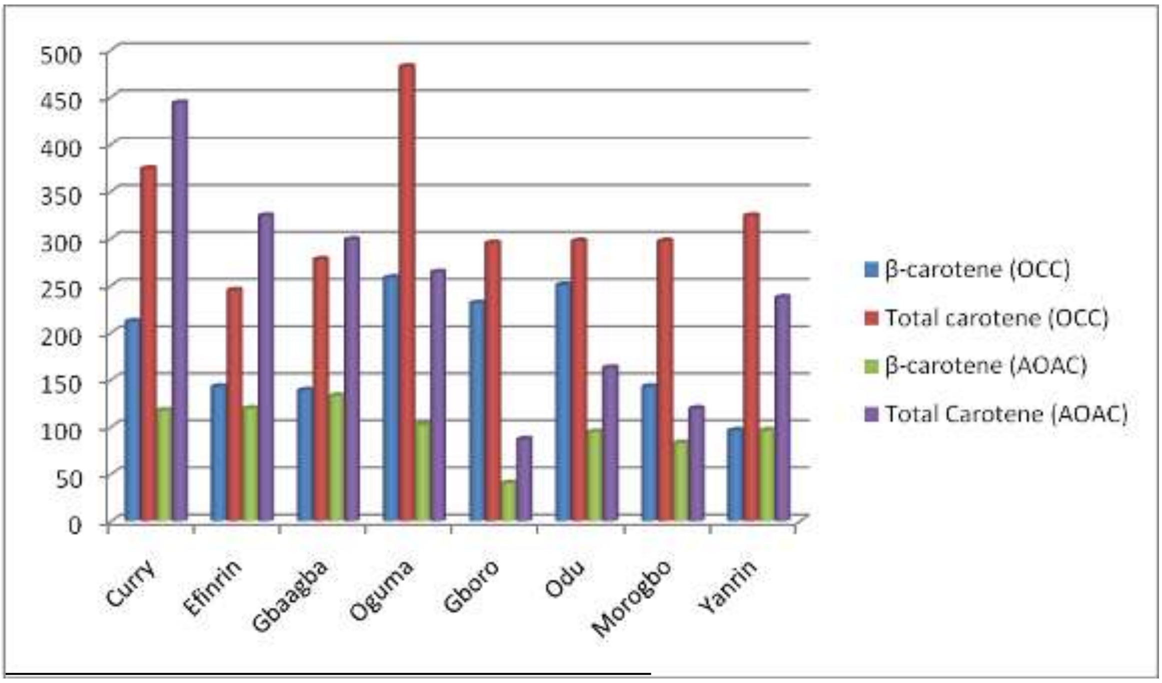

Figure 3: Beta-Carotene and total carotene content of selected vegetables (Open Column Chromatography (OCC) and AOAC methods) in µg/100g

ISSN: 2814-0508

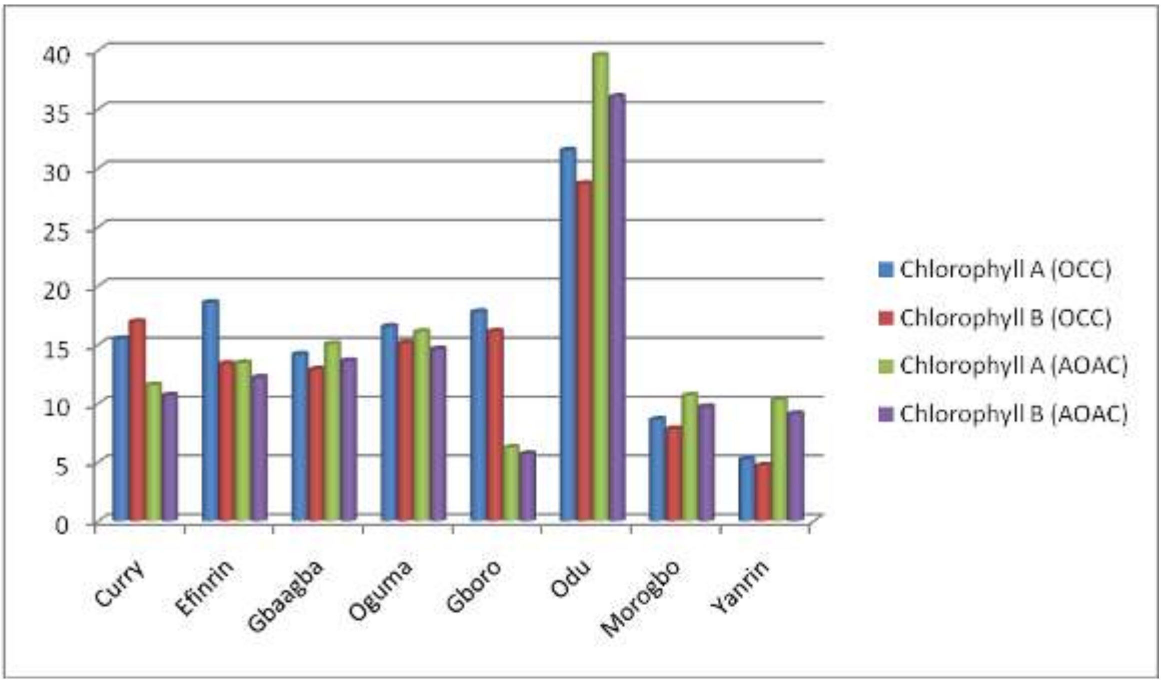

Figure 4: Concentration of chlorophyll A and B in selected vegetables (Open Column Chromatography and AOAC methods) in mg/g tissue

DISCUSSION

Vitamin C contents of the eight leafy vegetables are appreciable and fall between the acceptable recommendation range with the lowest in curry and highest in *morogbo*. Vitamin C ranged between 8.34 and 23.25mg/100g this was lower to the one reported by Adeguwa *et al*. (2011) on processed vegetables which ranged between 49.3 mg/100gto 104.1 mg/100g which may be due to the processing. Also at variance with vitamin C content obtained in the study of Lisiewskwa *et al.* (2006). *Morogbo* that is regarded as weed in most localities in the southwest had highest concentration of vitamin C and thiamine (Vitamin B_1), curry showed lowest concentration while *efinrin* had highest concentration of pyroxidine (Vitamin B 6) and was lowest in *oguma*.

Moisture contents in all the vegetables was very high, this is an indication that the vegetables will be very low in dry matter content hence, would be a good source of microelements. *Efinrin, gbagba* and *gboro* showed highest percentage of protein content while least values were observed in *oguma* and *morogbo.* Fat content was highest in *odu*, curry and *yanrin*, these vegetables are odourous and this is indicative of the presence of essential oils that have been observed in this vegetables. High significant value of fat in all vegetables analysed is an indication that they are good for consumption in keeping the body warm. Fats in food samples keeps the body warm even twice as that of carbohydrate. The presence of appreciable content of crude fibre and ash content showed that the vegetables were very good for consumption.

In comparing the concentration of beta-carotene and total carotene recovered from the two methods Open column method (96.45 to 258.49µg/100g; 244.99 to 482.26 µg/100g) was better than Association of Analytical Chemists (AOAC) method (40.52-133.1µg/100g to 119.6 to 443.68µg/100g) of analysis. The total carotene concentration was in agreement with the recovery in the work of Kimura and Rodriguez-Amaya (2003). It was at disparity with the range recovered in the research of Ahamad *et al*., 2007 though some of the vegetables were not leafy and High Performance Liquid chromatography was used which may be responsible for the result since it is a rapid, efficient and sensitive technique for carotenoid analysis. Podsedek, 2007 was of the opinion that leafy vegetables are indeed a rich source of beta-carotene which the present study confirmed.

AOAC method of analysis was better in the recovery of chlorophyll a than the open column method while open column method was better for the recovery of chlorophyll b. The result of the present study was lower than the content of both the chlorophyll a and chlorophyll b in the work of

Znidarcic *et al*. (2011); while the content were higher than that of Lisiewskwa *et al*. (2006). Chlorophyll a had higher content than the b variant in the present study.

CONCLUSION

The eight extincting leafy vegetables were rich in phytochemical, soluble vitamins, beta-carotene and chlorophyll. This is an indication that the vegetables had great potentials to improve human health and can be used to synthesis useful drugs that can cure diverse diseases. It is, therefore, recommended that the vegetables should be cultivated and that the populace should re-introduce it to our diet.

ABSTRACT

Many vegetable crops are underutilized despite their high nutritional values. Corchorus capsularis is hardly grown in Nigeria but only limited to its natural occurrence as weed in farmlands during rainy season. The cooked leaves form a slimmy sticky sauce which is consumed with starchy balls made from sorghum, millet and maize. In other parts of Africa, it is used to prepare several recipes in combination with pumkin, sweet potato, cocoyam leaves and cowpea. Due to its fast growing habit, draught tolerance and high nutrient it can serve as good alternative to Ceratotheca sesemoides. This paper, therefore, document agronomic potentials of C. capsularis being an orphan crop and its benefits in order to enhance food security in Nigeria.

Key words: *Corchorus capsularis*, under utilized crop, food security, agronomic potential

INTRODUCTION

Corchorus capsularis (white jute), an erect annual herb up to 1m tall with branches, globose fruits and it probably originates in southern China. It was brought from there to India and Bangladesh where, till today, its production is centred. In the late 18th and early 19th century the crop was brought to many other tropical countries, but only in Brazil has the introduction been successful. The failure of the crop in other countries than Brazil has been attributed to a wrong choice of cultivars and labour constraints. In tropical Africa it is reported as a wild or cultivated vegetable in many countries. It is a leading leaf vegetable in Côte d'Ivoire, Benin, Cameroon, Sudan and Zimbabwe. White jute is also cultivated as a leaf vegetable in the Caribbean, Brazil, India, Bangladesh, China, Japan, Egypt and the Middle East. It is cultivated for jute production in Asia (India, Bangladesh, China) but in Africa it is of no importance as a fibre crop, although the fibre may be used domestically as firewood. The fibre of *Corchorus capsularis* is less fine, soft and lustrous than that of *Corchorus olitorius*. The former is usually whitish, whereas the latter is yellowish to reddish (Fondio and Grubben, 2011).

USES

White jute is used as a leafy mucilaginous vegetable. When cooked the leaves form a slimy sticky sauce, comparable to okra. In Nigeria this sauce is found suitable for easy consumption of starchy balls made from cassava, yam or millet. A powder prepared from dried leaves is used to prepare this sauce during the dry season. The immature fruits, called bush okra, are also dried and ground to a powder for the preparation of this slimy sauce. In East Africa several recipes exist, it can be cooked with cowpeas, pumpkin, cocoyam leaves, sweet potato, meat, and flavoured with peppers and lemon. Root scrapings are used in Kenya to treat toothache, a root decoction as a tonic, leafy twigs in Congo against heart troubles, an infusion from the leaves is taken in Tanzania against constipation, and seeds in Nigeria as a purgative and febrifuge. *Corchorus capsularis* leaves contain antioxidative phenolic compounds, of which 5-caffeoylquinic acid is the most important. Some ionone glucosides have also been isolated from the leaves; they showed inhibitory activity on histamine release from rat peritoneal exudate cells induced by antigen-antibody reaction (Ohtani *et. al.,* 1995)

LIFE CYCLE

Growth of *Corchorus capsularis* is fast. In short day conditions flowering starts about a month after emergence and continues for 1–2 months, depending on type and conditions. The flowers are usually self-pollinated, but cross-pollination up to 10% occurs. After about 3–4 months, the fruits are ripe, the leaves drop and the plant dies (Burkill, 2000).

CULTIVATION

Most farmers have no access to improved seed, but harvest from the wild. For a good seed yield of 25 g per plant, a spacing of 50 cm between and within the row is recommended. Commercial seed production may be 600 kg/ha. The seed is ripe when all the leaves have dropped. For own on-farm seed production, the stems with fruits are harvested, and after drying in the sun they are kept until the next season. In villages in the north of Côte d'Ivoire, the women conserve the fruits in the kitchen above the fireplace. Fruits on abandoned plants in the field also still contain viable seed until the next rainy season. These fruits open at the onset of the rains and the seeds spread. Well-dried seed keeps a high germination capacity for several years. One g contains about 470 seeds. Fresh and sometimes old seed shows dormancy caused by impermeability of the seed coat. This is a major problem for Jew's mallow cultivation. To suppress the dormancy, it is recommended that the seed tied in a piece of cotton cloth be immersed for 5 seconds in almost-boiling water before sowing. Another method is scarification with sandpaper (Mwaikambo, 2006).

In traditional field cultivation, the farmers broadcast seed without any consideration concerning the optimal density. Peri-urban vegetable farmers produce Jew's mallow on beds in monoculture. Direct sowing is mainly applied for once-over harvest by uprooting or low cutting at soil level. Sowing is done in lines 30–50 cm apart and with spacing 10–15 cm in the rows. For the more common harvesting by repeated cuttings, 10–20 g seed per 10 m² is sown in a nursery in well-loosened soil. When the seedlings are 5–10 cm tall, they are transplanted at a spacing of 10–20 cm in the row and 30–50 cm between the rows (Norman, 1992)

HARVESTING

The first harvest by cutting shoots 20–30 cm long may take place 4–6 weeks after transplanting at a height of 10–20 cm above the ground. This cutting stimulates the development of side shoots. Subsequently every 2–3 weeks a cutting may take place, in total 2–8 cuttings. For a once-over harvest from a direct sown crop the plants are uprooted or cut at ground level when they are 30–40 cm tall, 3–5 weeks after emergence and before development of fruits. The plants are bundled for marketing. In intercropping systems farmers tend to harvest at irregular intervals.

ABSTRACT

The rising cost of conventional fuel necessitates exploration of other cheap, renewable and sustainable energy sources especially in Sudano-Sahelian region of Nigeria. Eucalyptus is one of the common tree species in the region, it leaves falls every day littering the environment and most times burnt after cleaning the environment which in turn emits CO_2. Hence study was carried out on biogas production using cow dung, eucalyptus wastes and mixture of cow dung/eucayptus to evaluate quality of biogas produced. Locally made digesters (10 L plastic buckets) were used, slurries were prepared at mixing ratio, waste to water (cow dung 3kg: 3000cm^3, eucalyptus 1kg: 5000cm^3 and mixture 2kg: 4000cm^3). For each sample digesters were fed in triplicates and subjected to anaerobic digestion for 6 weeks. Mean values of weekly biogas produced was measured using water displacement. Cow dung has the highest total volume of biogas produced (9416.34cm^3), mixture of cow dung/eucayptus (5793.33cm^3) and then eucalyptus (3780cm^3). Data obtained were subjected to (ANOVA) which shows no significant difference among the substrates used at ($P<0.05$). Biogas produced was also analyzed using NDIR Gas analyzer which revealed percentage of gases that comes with methane and caloric value. Methane content/caloric value recorded were 53.35% /249.58 KJ/m^3, 34.79% / 125.98 KJ/m^3 and 34.58% / 124.60 KJ/m^3 for eucalyptus, mixture of cow dung/eucayptus and cow dung respectively. Temperature recorded during the period was between 29.1^{o}C - 32.1^{o}C. This research has shown that biogas produced from eucalyptus has substantial methane content than cow dung and mixture of cow dung/eucayptus.

Key words: *Eucalyptus camaldulensis*, composition, biogas, cow dung.

INTRODUCTION

The use of fossil fuels as primary energy source has led to global climate change, environmental degradation and human health problems (Adeniran *et al.,* 2014). Also, improper waste management is one of the major problems confronting every development. This is because increase in industrial, commercial, agricultural and environmental activities has resulted in the generation of large quantities of wastes (Adeniran *et al.,* 2014). These wastes, when not properly managed contribute to unhygienic environmental conditions that breed pathogenic microorganisms (Ogbene *et al.*, 2019). Apart from the health implications, wastes make an environment unpleasant and unattractive. However, these wastes can be managed properly by conversion into useful and more environment-friendly forms called biogases. Biogas typically refers to a gas produced by the breakdown of organic matter in the absence of oxygen (Anunputtikul and Rodtong, 2004). It is a renewable energy source, like solar and wind energy. Furthermore, biogas can be produced from regionally available raw materials and recycled waste and it is environment friendly and carbon IV oxide (CO_2) neutral. Biogas is produced by the anaerobic digestion or fermentation of biodegradable materials such as manure, sewage, municipal waste, green waste, plant material, and crops (Kaygusuz and Kaygysuz, 2002).

Biogas is a flammable gas produced when organic materials are fermented under anaerobic condition (Sagagi *et al.,* 2009). It contains methane and carbon (IV) oxide with traces of hydrogen sulphide and water vapor. It burns with pale blue flame and has a calorific value of between 25.9-30J/m^3 depending on the percentage of methane in the gas. The gas is called by several other names, such as: dung gas, marsh gas, gobar gas, sewage gas and swamp gas (Dangoggo and Fernando, 1986). In biogas production, the conversion of complex organic matter to methane and carbon dioxide is possible mainly by the actions of different group of microorganisms, with the microbial community of biogas comprised essentially of bacteria and fungi and other groups of protozoan (Idi *et al.,* 2020) The essential microbial complex is comprised of hydrolytic bacteria, fermenting bacteria, acetogenic bacteria and methanogenic bacteria and these groups of microorganisms have been reported to establish synthrophic relationships where the later members of the food chain depend on the previous for their substrate but may also have significant metabolic products (Eze and Agbo, 2010).

A non-dispersive infrared sensor (NDIR sensor) is a simple spectroscopic sensor often used as a gas detector. It is non dispersive in the sense of optical dispersion since the infrared energy is allowed to pass through the atmospheric sampling chamber without deformation. The main components of an NDIR sensor are an infrared source (lamp), a sample chamber or light tube, a light filter and an infrared detector. The IR light is directed through the sample chamber towards the detector. In parallel there is another chamber with an enclosed reference gas, typically nitrogen. The gas in the sample chamber causes absorption of specific wavelengths according to the Beer–Lambert law and the attenuation of these wavelengths is measured by the detector to determine the gas concentration. I.e. The gas is pumped (or diffuses) into the sample chamber, and gas concentration is measured electro-optically by its absorption of a specific wavelength in the infrared (IR). The detector has an optical filter in front of it that eliminates all light except the wavelength that the selected gas molecules can absorb. (Korotcenkov, 2013)

Eucalyptus camaldulensisDehnh is widely planted as an exotic in many parts of Nigeria. It is the most widely planted tree species in semi-arid and arid environments it is very strong, durable and useful timbers which can be put to a wide variety of uses. Much attention has been focused on biomass from grass. However, *Eucalyptus* species is one of the most promising types of cellulose feedstock for biogas production due to its high cellulose content (Yu *et al*., 2010). In addition, these biomasses do not form human and animal food sources. *In Nigeria, it is largely grown for the production of fuel wood, poles and posts and also in mixture with other tree species such as Azadirachta indica (Neem), for the establishment of shelterbelts. (*Midgley *et al., 1989).*

MATERIALS AND METHODS

Samples Collection

Cow dung was collected in a clean bag from Kofar marke area of Sokoto and transported to Sokoto Energy Research Center, Usmanu Danfodiyo University Sokoto, Nigeria. *Eucalyptus camaldulensis. Dehnh* waste was collected in a clean bag from Savanna Forestry Research Station Samaru – Zaria, Kaduna Stateand transported to Sokoto Energy Research Center, Usmanu Danfodiyo University Sokoto, Nigeria where it was sun dried for 7 days and pulverized into powder using mortar and pestle (Galbe M. and Zacchi G. 2007).

Pretreatment of Eucalyptus Waste

The grinded powdered sample of the Eucalyptus waste was put in a polythene bags and buried underground for 14days to mesorize (Nnaji 2015).

Preparations of Slurry

Three thousand gram (3000 g) of fresh cow dung was mixed with 3000 ml of water in a ratio of 1:1. The mixture was agitated thoroughly. One thousand gram (1000 g) of pulverized Eucalyptus was mixed with 5000 ml of water in a ratio of 1:5. For the mixture, one thousand five hundred grams (1500 g) of the fresh cow dung and five hundred grams (500 g) of pulverized eucalyptus was mixed with 4000 ml of water in a ratio of 2:4. All were agitated thoroughly and transferred into separate digesters (10 litters) and tightly covered with silicon sealant and araldites to create anaerobic condition. Each sample was replicated 3 times (kigozi *et al.* 2014), (Sagagi *et al.,* 2009) and (Akhator *et al.,* 2016). pH of the slurries was also taken before and after digestion.

Measurement of Biogas Production

Volume of biogas production was measured using measuring cylinder by water displacement method. Mean values of weekly biogas production were taken as shown in plate 1, together with the temperature variations for 6 weeks' retention time (Oghenefejiri *et al.,* 2016).

ISSN: 2814-0508

Plate 1: Set- Up of Locally Made Rubber Digesters

Non Dispersive IR Gas Analysis

Biogas samples (4000cm^3) were collected using two urine bags (2000cm^3) that were connected to two separate digesters for each of the three samples and was taken to Department of Chemical Engineering, Ahmadu Bello University, Zaria for NDIR analysis using Gas Analyzer (Gasboard-3100P). The analyzer measured concentration of CO, CO2, CH4, H2 and O2 in the sample simultaneously and also calculated caloric value automatically.

Gas analysis was carried out according to manufacturer's instruction, where biogas sample was pumped into the sample chamber and gas concentration was measured electro-optically by absorption of specific wavelength in the infrared (IR). The IR light was directed through the sample chamber towards the detector. The detector has an optical filter that eliminates all light except the wavelength that the selected gas molecule can absorb. Ideally other gas molecules do not absorb light at this wavelength, and do not affect the amount of light reaching the detector. The detector measures the attenuated signal depending on the amount of gas absorption and it is proportional to the measured gas concentration (Barati 2017) and (Rajaefar *et al.,* 2017).

Analysis of Variance

The data collected were subjected to ANOVA using Minitab 17 and mean differences in total gas yield were separated using least significant difference (LSD) at P<0.05 level which shows there is no significant difference in the volume of biogas produced from cow dung, eucalyptus and mixture of cow dung/eucalyptus

RESULTS AND DISCUSSION

The result obtained from the biogas production as shown in Table 1, indicates that highest biogas yield recorded was from cow dung (6376.34cm^3) at week 3, followed by Eucalyptus waste (2383.33cm^3) at week 4 and then mixture (2259cm^3) at week 3. This trend shows that the production potentials of the samples differ, which is in agreement with the work of Baki, *et al.,* (2004) and Arinze, *et al.,* (2005). Low biogas yield recorded from eucalyptus waste could be due to high lignin content and the nature of the substrates. However, low biogas yield observed in the first week for cow dung, first and second week for eucalyptus and mixture could be due to lack of activity of methanogenic bacteria and at those weeks the development of such bacteria was not completed. The volume of biogas yield for Mixture at week four start decreasing unlike other samples which could be due to mixing effect from the two different samples. Similarly, at 5th week, a decline in the biogas yield was recorded and this is due to the lower activity of bacteria which results due to shortage of ingredients needed for it survival.

Table 1: Weekly Biogas Produced (cm^3)

Retention time (weeks)	Cow dung	Eucalyptus	Mixture	Average Temp. (^0C)
1	53.67±0.08	NGP	NGP	29.1
2	2950.33±0.99	NGP	134.33±0.35	31.1
3	6376.34±8.56	681±0.14	2259±0.14	31.5
4	36±0.11	2383.33±4.12	1700±0.00	30.6
5	NGP	622±75.0.36	1700±0.14	31.2
6	NGP	93.67±0.17	NGP	32.1
Total	9416.34	3780.00	5793.33	

Results are mean of triplicate ± SD; NGP= No Gas Production

Result of ANOVA (Two way) for the biogas produced as shown in Table 2 revealed p-value as 0.346 which is greater than (0.05), hence there is no significant difference ($P<0.05$) in the biogas yield from the three different samples, thus the volume of biogas produced from the three samples are the same.

Table 2: Analysis of Variance (ANOVA) for Biogas Produced

Source	DF	Adj SS	Adj MS	F-Value	P-Value
Period (WK)	5	29005487	5801097	7.74	0.000
Sample	2	1628037	814019	1.09	0.346
Error	46	34498521	749968		
Lack of Fit	10	34494723	3449472	32696.42	0.000
Pure Error	36	3798	106		
Total	53	65132045			

Different gases are produced during the production of biogas from cow dung, Eucalyptus and mixture, the gas analyzer (Gasboard-3100P) used has the capacity of detecting only five different gases, and these include: CO, CO_2 CH_4, O_2 and H_2 as shown in table 3 below. Biogas generated from Eucalyptus leaves recorded highest methane content (53.35%) which is the target composition and lowest come from cow dung (34.58%). which is in agreement with the work of Joao, *et al.,* (2011). This could be due to the nature, and composition of Eucalyptus species. The gas analyzer (Gasboard-3100P) also measured calorific value of the biogas.

Table 3: Percentage Composition of Some Gases in the Biogas Produced

Sample	Percentage composition (%)			
	CO	CO_2	CH_4	H_2
Cow dung	0.03	9.97	34.58	0.46
Eucalyptus	0.26	11.48	53.35	0.00
Mixture	0.00	10.84	34.79	1.11

The results as obtained from the NDIR Gas analyzer as shown in Table 4 indicates higher heating values of the biogas produced from *Eucalyptus camaldulensis. Dehnh* (249.58KJ/m^3) and lowest from Cow dung (124.60KJ/m^3). The Eucalyptus leaves contain highly nutritious rich organic substances that are suitable for sustaining microbial life in an anaerobic fermentation process, and transform substrates into biogas. These results were in accordance with the work of Joao, *et al.,* (2011). High caloric value is due to high methane content from the biogas produced from Eucalyptus, and this shows the potentiality of biogas generated from Eucalyptus leaves as a cooking gas.

Table 4: Caloric Values of Biogas Production from the Substrates

Sample	Caloric value (KJ/m^3)
Cow dung	124.60
Eucalyptus	249.58
Mixture	125.98

pH of the sample is another factor that affects biogas production. pH value is of paramount importance especially during digestion to provide enable environment for the production of the biogas. Table 5 shows the pH values before and after of the substrate samples. However, the optimum pH range for biogas production has been reported as 6.0 – 7.8 before digestion and 5.6 – 7.8 after digestion. (Garba and Sambo 1992). Based on this the results of pH as shown in table 5 above indicates the samples used in this research were having pH which provides favorable environment for effective bio digestion of the substrate. The pH values were in agreements with the work of Garba and Sambo (1992).

Table 5: pH values of the substrates

Samples	Before digestion	After digestion
Cow dung	7.12±0.01	5.14±0.01
Eucalyptus	7.83±0.01	6.73±0.01
Mixture	6.71±0.01	5.79±0.01

Results are mean of triplicate ± SD

CONCLUSION

Total volume of biogas recorded for 6 weeks' retention time were (9416.34cm^3), (5793.33) and (3780.00cm^3) for cow dung, mixture and eucalyptus respectively, indicating that all the substrates used in the study were good candidates for biogas generation. Furthermore, ANOVA (Two way) for the volume of biogas produced revealed *p*-value as 0.346 hence no significant difference ($P<0.05$) in the biogas yields recorded for the three different substrates. ND-IR analysis revealed high methane content and caloric value from eucalyptus (53.35%) (59.65Kcal/m^3) and least from cow dung (34.58%) (29.78Kcal/m^3). This has shown the quality of biogas generated from leave litters of *Eucalyptus camaldulensis. Dehnh is superior compared to other subtrates used*. pH of the substrates recorded were within the recommended value of 6.0 – 7.8 before digestion and 5.6 – 7.8 after digestion. This has proven the noble potentiality of the said plant as source of biogas which has not been well exploited in the study area.

RECOMMENDATIONS

The use of biological waste materials is receiving attention for their effectiveness in biogas production because of less or zero emission of carbon. Therefore, based on this research, the following further works are recommended:

1. Research on the applications of biogas produced by the substrates.
2. More research on the activities of microorganisms that perform the action of biodegradation during biogas production.
3. Large scale production of efficient digesters, cylinders and burners for domestic activities
4. Similarly, based on the observations and encouraging results from this research, use of Eucalyptus wastes for biogas generation should be given more attention in areas where the wastes are in abundance.

ABSTRACT

This paper analyses the potential impacts of climate change on apple production in Marondera District, Zimbabwe. The Climate Change Wizard online tool was used to make historic and mid-century projections on temperature (ºC) and precipitation (mm) the major drivers of crop production in the country. The A2 scenario extracted from Special Report on Emission Scenarios (SRES) was used. The scenario was run using four different models to project monthly outputs. The model outputs were related to the observations made on the flowering of an 18year old apple orchard. It was observed that the flowering season for the apple cultivars is commencing earlier than previously. The projections show an increase in annual precipitation, increasing mean monthly maximum and minimum temperatures. Marondera will thus be characterized by hot summers and warmer winters as shown by increasing minimum temperatures around May to August. The increasing temperatures will make the environment unsuitable for apple production in the near future. It will also have a negative impact on the expansion of apple production in the country as region one is also shrinking due to climate change.

Key words: climate change, apples, temperature, precipitation, projections, flowering

INTRODUCTION

Modern satellite data suggest that about 50-83 % of the land surface has been physically transformed by human activities (Bologna, 2008). Global warming has been attributed to human induced activities, which include the production and use of fossil fuels and land use (UNFCC, 2008). The warming of Earth's climate is clear as evidenced from increases in global average air and ocean temperatures, sea level rise and melting of ice and snow in the arctic (IPCC, 2007). Reports on current scientific research indicate that projected events are becoming more likely than before.

The current climate records for Zimbabwe, shows some considerable spatial and temporary variability which have been characterized by no specific trends in rainfall patterns, intensities and distribution (Unganai 2009). There has been an increase in the occurrence of extreme weather events, the cyclones (Eline and IDAI) and droughts (Mutasa 2008) across the country. Records from July 2012 from the Zimbabwe Met Offices recorded temperature as low as -3ºC (http://www.chronicle.co.zw/) in May when the maximum effect of winter is normally expected in June and July. Zimbabwe as compared to other African countries is highly vulnerable in the world due to widespread poverty and limited coping strategies (UNFCC, 2007). This is because Zimbabwe is heavily dependent on rain fed agriculture and climate sensitive resources (Chaguta, 2010).

The country was divided into five agro ecological regions based on rainfall patterns rainfall patterns and crop productivity (Vincent and Thomas, 1960). Agro-ecological zones, as defined by FAO (1978), are land areas representing unique combinations of homogenous agro-climate, ecology, soil units and agricultural activities Natural Region I (NRI) covered approximately 2% of the land area and had the highest rainfall. It was an area of specialized and diversified farming with plantation forestry, fruit and intensive livestock production with tea, coffee and macadamia nuts being grown in frost-free areas. Natural Region II (NRII) covered about 15% of the land area, receiving lower rainfall than Region I. Nevertheless, it was suitable for intensive farming based on crops or livestock production. The remaining natural region from III to V covered a range of farming from semi-intensive farming to extensive respectively. However, current studies on Zimbabwe's agro ecological regions indicate a shift in the agro-ecological zones, which has been attributed to climate change (Zimbabwe Meteorological Services Department, 2002; Chikodzi *et al.,* 2013). The increase in temperatures and unreliable rainfall has seen the shrinking of NRI and NR11 and the expansion of NRIII. Stations like Chinhoyi, Chibero and their surroundings previously in NRII were moved to (NR III) Government of Zimbabwe (2020).

Apples best grow where temperatures do not rise above 25°C for them to have a good flavour. In Zimbabwe these temperatures are best approximated in Nyanga. However, NRII, specifically Marondera, has the potential for apple and other deciduous fruit tree production in the country by virtue of its cooler climate. Apple and any other fruit research in Zimbabwe are relevant to support the countries' food and nutrition policy which was launched May 2013, horticulture recovery plan 2020. The Policy aims to ensure adequate food and nutrition security in Zimbabwe for all people at all times. Statistics show that one out of every three children is chronically malnourished, 25% of all deaths of children under the age of five are attributed to nutritional deficiencies and 47% of women are anemic.

Apple *(Malus domestica/Malus pumila),* Maepuru [S], Ama Apula [N] is classified under the group of pome fruits in the same family with pears and quince. Apples have a dormant winter period that requires cold temperatures for the tree to properly break dormancy in spring. Apples are grown from late winter (July to August) blossom and harvested from November through to late March in Zimbabwe. The fruits require a period of chilling (exposure to temperature of 7.2°C) during the winter period for them to flower adequately. Varieties that require 500 or less of chilling hours for them to flower are called low chilling requirement apples. These cultivars are best suited in areas such as Marondera, Rushinga, Domboshawa, Harare and areas with similar microclimates. The cultivars that need chilling hours of 500 to 800 hours are called medium chilling requirement apples, while those that require 800 to 1200 chilling hours are called high chilling requirement apples.

There has been some positive progress in Nyanga lately as reported by the Apple Association of Zimbabwe (www.freshplaza.com) that apple farming has changed the lives of people with about 170ha under production, about1 200 individuals employed and about 8000 households being supported. Past studies on apples by the Horticulture Research Institute also proved that Marondera was a site closely comparable to Nyanga and could be exploited for apple production. It was also proved high chilling apple varieties could thrive in Marondera, though with special treatment of dormancy breaking chemicals such as Dormex (mineral oil) or winter oil (DNOC 3%) in June/July. The main objective of this study was to assess the potential impact of climate change on the future of apple production in Marondera District, Zimbabwe.

MATERIALS AND METHODS

Study Area: Climate change projections were made for Marondera, Mashonaland East Province of Zimbabwe. Marondera is in the highveld, latitude 18° 11' longitude 31° 28' E. Marondera is classified under Natural region IIb at an altitude of 1630 - 1800m above sea level. The observations were done at the Horticulture Research Institute (HRC). Historically the province was characterised by a subtropical climate, which was well suited for the cultivation of wide range of temperate and sub-tropical crops. The average minimum temperatures range from 5.1°C to 14.2°C in January. HRC has a mean average day-length of 13.2 hours in summer to 11.1 hours in winter. HRC is also characterised by ground frost during the months of June and July with sporadic devastating frosts occurring in September. Rainfall averages 873 mm per year, temperature mean maximum are form 19.5°C (July) to 24.6°C (January). Hot summer is between September and December. October is the hottest month of the year with maximum temperatures above 30°C.

Modeling: The Climate Change Wizard Application (Nature Conservancy 2009) was used to make projections. The wizard allows the user to choose a country or state and both access how climate has changed over time and to project what future changes are predicted to occur in a given area. Users can view historic temperature and rainfall maps from anywhere in the world, view future prediction of temperature and rainfall around the world based on scientifically vetted model projections and view and download climate change maps.

A polygon was drawn on the map to pre-define Marondera district. Parameters to be used for projections were selected, the monthly temperature and precipitation. The historical projections were averages during 1961-1990 period and future projections were made for the mid-century period from 2046-2065. The A2 emission scenario (IPCC 2007) was used. The A2 scenario family describes a very heterogeneous world were the underlying theme is self-reliance and preservation of local identities. In this analysis, four different models, GFDL-CM2.1, IPSL-CM4, MICROC3.2, and CGCM3.1 were run to come up with an ensemble average. The models are from

USA, France, Japan and Canada respectively. It has been observed that when a number of models are used, the average of these models performs better than any individual model (Santer *et al*., 1990).

Projections were made on:

i. Average low temperature
ii. Hottest temperature ºC
iii. Coldest temperature ºC
iv. Number of cold days (% of time that daily maximum temperature values are below the reference period (1961-1990).
v. Number of cold nights
vi. Number of warm days
vii. Number of warm nights
viii. Total Precipitation, rainfall mm

An inventory of apple cultivars growing in Marondera was created at HRC in 2008 taking note of the name, origin, physical and fruiting characteristics. A total number of 26 apple cultivars were observed over a period of 6 years from 2008 to date. Since the trees were old (about 18 years), observations were made only on the time of flowering as they had already reached their full yield potential. Early apple varieties we had Anah, Mayan, Elah and Michal of Israeli Origin. These cultivars normally flowered from the 4th week of July getting onto full bloom in the 1st week of August. Yields ranged from45-50 kg per tree (Anna and Mayan) and about 50-60 kg/tree (Ellah).

Table 1: Apple cultivars observed at HRC and their origin, flowering times, fruiting times and total yield (kg) per tree of the high chilling apple cultivars

High chill apple cultivars (sprayed with a dormancy breaking hormone for them to induce bud break)			
Golden Delicious	West Virginia, USA	1st week of October to 3rd week of October	**Fruits:** From October to February **Yield:** 60 to 90 kg/tree
Fuji	Japan	1st week of September to 4th week of September	**Fruits:** From September to February **Yield:** 60- 80 kg/tree
Mollies Delicious	Europe	1st week of September to 4th week of September	**Fruits:** From September to February **Yield:** 50-60 kg/tree
Jomured and Starking	Europe	1st week of September to 4th week of September	**Fruits:** From September to February **Yield:** 25-30 kg/tree
Royal gala	New Zealand	3rd week of September to 1st week of October	**Fruits:** From October to February **Yield:** 50-60 kg/tree
Goldjorn and Primicia	USA	1st week of September to 4th week of September	**Fruits:** From September to February **Yield:** 20-30 kg/tree
Majorie pie	USA	1st week of September to 4th week of September	**Fruits:** From September to February **Yield:** 30- 45 kg/tree

RESULTS

Apple observations

Overally the observations made indicate early flowering across the different cultivars. The trees go into flowering about two weeks earlier than their historic performance. The flowering season has shrunk by about 2-3 weeks for all the cultivars. The low chilling cultivars continue to come into flower first and the high chilling last. There is however a decrease in the number and quality of flowers during the season especially for the high chilling varieties. This has resulted in reduced fruits per tree and thus low yields.

Modelled Results

The total projected annual precipitation for the mid -century is expected to increase to 923mm from 912mm. The monthly precipitation is evenly spread with the winter season receiving the least precipitation. The projected monthly rainfall shows a decrease from September to December as compared to the historical average. It is projected that the highest mean monthly precipitation will still fall in January (225mm) showing an increase from the historical average (213mm).

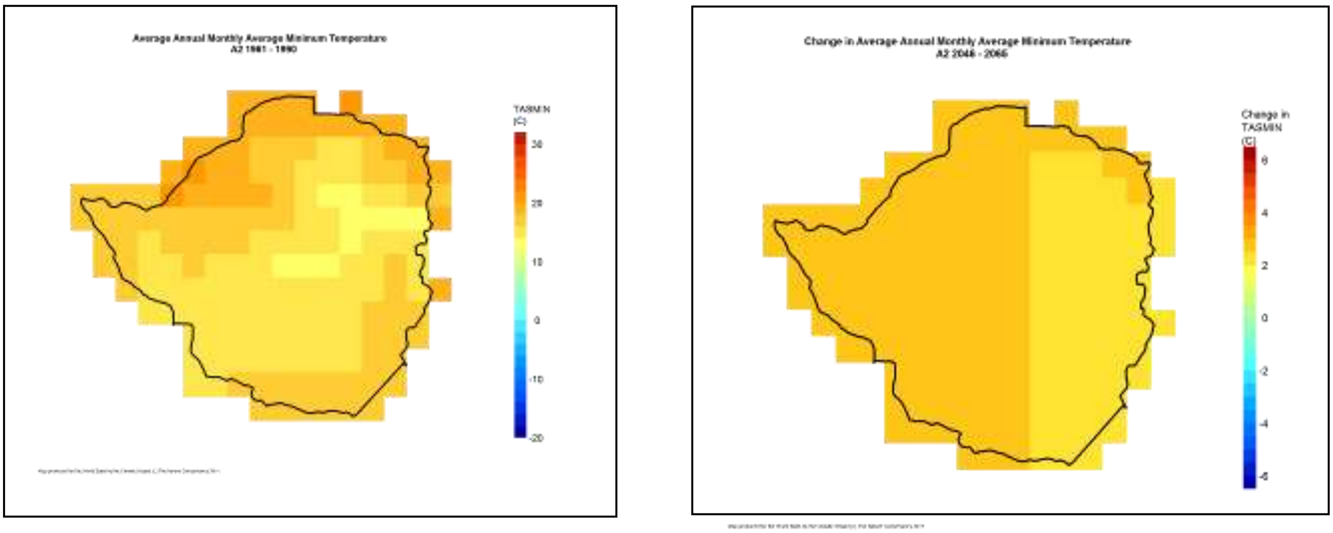

Figure 5: The historical and mid-century mean minimum temperature (ºC) projections for Marondera district

There is an overall increase in the minimum and maximum temperatures as we progress into the mid -century. The historical mean maximum annual temperature is projected to increase by about 2.7 ºC to 26.60 ºC. October will be the hottest month with about 30 ºC. The historical mean minimum annual temperature is projected to increase by about 2.46 ºC in the mid-century to 14.01 ºC. It is projected that the historical month receiving lowest minimum temperature will shift from June to July (Figure 3). The increase in temperatures is also illustrated in (Figure 2) as shown with the gradation from the lighter yellow colouration to deep orange.

The historical minimum temperature for June, July and August was 6.63 ºC, 5.80 ºC and 7.78 ºC respectively. Minimum temperature projections for the same months show an increase to over 8 ºC. The number of cold days, (% of time that daily maximum temperature values will be below the reference period is projected to decrease from 10% to between 2-4%. The number of cold nights (% of time that daily minimum temperature values will below the reference period is projected to decrease from about 10% to between 1 -3% for all the months. The decrease by 1% takes half the proportion.

DISCUSSION
